**Snyder's Obstetric Analgesia and Anesthesia**

Because the most controversial problem in obstetrics today is *relief of pain in labor,* this brand new and thoroughly up-to-date book is certain to assume immediate importance as a reference source for obstetricians, pediatricians, anesthetists, and general practitioners who have even a passing interest in obstetrics.

In clear and straightforward style the author evaluates the various anesthetic and analgesic agents in respect to: 1. potency in the relief of pain; 2. effect upon the fetus; and 3. effect upon the mother, *especially the labor mechanism.* He also provides 200 pages of vitally important information on respiratory injuries of the child (atelectasis, asphyxia, etc.)

By Franklin F. Snyder, M.D., Associate Professor of Obstetrics and Associat[illegible] of Anatomy, Harvard Medical School. 401 pages, 6" x 9", with 114 illustrations [illegible]

# Wiprud's Business Side of Medical Practice

## How to Save Time and Money!

HERE, in this handy 232-page book, is *the information you need* to handle intelligently the business aspects of your practice. Here is expert and absolutely reliable advice on organizing your time, systematizing office routine, keeping financial and case records, writing effective collection letters to delinquent debtors (actual sample letters are given), testifying in court, making speeches, planning an intelligent investment program, and many other equally important topics.

This *New (2nd) Edition* is, of course, completely up-to-date in every way (among the new chapters is one on Group Medical Practice). Every doctor should have a copy, for the use of his secretary as well as for himself, because no doctor has had the time or opportunity to learn modern business methods. *To assure yourself that you are not wasting time and money through inefficient office methods, order this book today!*

By THEODORE WIPRUD, Executive Director and Secretary of the Medical Society of the District of Columbia and Managing Editor of the Medical Annals of the District of Columbia. 232 pages, 5½″ x 8″. *Just Ready.*
*New (2nd) Edition—Just Published.*

**Contents**

Personal Efficiency
Building a Private Practice
Office Management
Necessary Financial Records
Case Records and Filing
Proper Handling of Patients' Accounts
Doctors' Bills and the Law
The Charity Patient
Investments and Insurance
Wills and Estates
The Doctor in Court
Preparation of a Manuscript
Public Speaking
Relations with the Press
The Doctor and Public Affairs
Opportunities for Leadership
On Conducting a Meeting
Fair Competition Among Physicians
Group Medical Practice
The Doctor Looks to the Future

# FURTHERANCE OF TREATMENT OF DIABETES MELLITUS

ELLIOTT P. JOSLIN, M.D.
Boston

## DIABETES THEN AND NOW

Fifty years ago we struggled to keep patients alive, but now we strive to keep them healthy. Then two thirds (63.8 per cent) of our patients died of diabetic coma, but today death from coma is so rare (1.9 per cent) that a certificate with this diagnosis should attract the attention of the medical examiner. Then, few in the first thirty years of life lived long enough to die of arteriosclerosis, but now even up to the age of 40 this is the most prominent cause of death, and of our patients of all ages over two thirds (69.1 per cent) succumb to it. Yet during the first fifteen years of this century, we felt decidedly more hopeless when confronted with a case of diabetic coma than we do today with the problem of arteriosclerosis. Coma is distinctive of the diabetic person, but arteriosclerosis is fatal alike to both diabetic, 69 per cent, and nondiabetic persons, 60 per cent, and the riddle to solve is why the former experience it prematurely and more rapidly than the latter. Decipher that and the lives of 143,000,000 nondiabetic persons in the country can be prolonged. Diabetic persons in the United States constitute a mass experimental group for the study of arteriosclerosis. To help one diabetic person keep young is to postpone growing old for 70 nondiabetic persons.

## PESSIMISM VERSUS OPTIMISM

Since pessimism is so rife in any discussion of prevalence of arteriosclerosis in the diabetic person, let us meet the situation head on to see if we have reached an impasse. At any rate, we have carried our diabetic patients up into the arteriosclerotic zone, for now on the average they die at 64 years instead of 44 (1898-1914), with a duration of the disease so long, fourteen and four-tenths years, that any of them contracting it at 62 years or later must exceed the normal life expectancy or else injure our duration statistics. There have been four notably pessimistic articles. Dolger[1] studied 20 patients with diabetes of twenty-five years' duration, and among these there was not one who escaped vascular damage as shown by retinal hemorrhages and albuminuria or hypertension, or both, in varying degree. But his point of view is handicapped by his contact exclusively with patients of other doctors, yours and mine, doubtless poorly treated, because he graduated from the medical school only fifteen years ago. I like to think that when he has been in practice ten years longer and followed up his own cases intimately for a quarter of a century he will report more encouragingly. A second contribution stems from Rosenbusch,[2] a pediatrician in Zurich, who paints so dark a picture from his own clientele of 88 cases in childhood, of whom 24 were dead, that cardiovascular-renal disease appears almost inevitable. But I suspect that this writer did not have a fair show in the treatment of his children. Reading between the lines, I judge that often insulin and food were deficient and their family background in many instances was not conducive to health. Chute[3] of Toronto described 123 cases in childhood in which diabetes developed prior to 1932. Of these 52 subjects were living, 58 dead and 13 untraced. Of the 29 who survived twenty years, 24 were living. These persons showed pronounced evidence of degenerative lesions, arteriosclerosis, albuminuria and retinitis. These complications are present to a lesser degree in the group surviving fifteen years. The conclusions of Dr. Priscilla White and her associate[4] on detailed investigation of 220 patients among 387, with the disease for twenty or more years and with onset in childhood before the age of 15 years, were appalling, because only 17 were free from vascular disease.

On the optimistic side of the ledger is the fact that in 17 cases of childhood diabetes there was no evidence of arteriosclerotic degenerative lesions as revealed by studies of the eyes by ophthalmologists, vessels by roentgenologists and careful physical examinations by us. Moreover, there are at least 4 patients with onset in childhood who, after twenty-five years of the disease, are likewise perfect and to whom a Victory Medal, designed by Amelia Peabody, has been awarded. When one considers that these are patients with onset antedating insulin therapy or in the first one or two years of its use, when diets were notoriously deficient in carbohydrate and calories, who can gainsay that succeeding statistical investigations will reveal a brighter picture? An analysis of the treatment in these Victory Medal cases will be published, and it is hoped that there will be many other patients to whom the medal can be granted by the Diabetic Fund. Suffice it to say now that thus far the medalists have been patients who have carefully observed treatment, often meticulously, and have had

most favorable home surroundings. Boyd and Jackson[5] from Iowa City, with a smaller number of cases but with most detailed studies, found the carefully controlled patient the one most complication free. This thesis for years has been supported by Allen.[6] At any rate, it is evident that diabetes in childhood is not to be a modern Sodom and Gomorrah.

Gangrene is an outstanding complication of arteriosclerosis, and yet, in our series since the period 1922-1929, gangrene as a cause of death has dropped from 8.6 to 1.9 per cent in the period 1944-1948, and that in the face of the fact that the duration of the diabetes had increased five years. Gangrene is only one aspect of sclerotic disease, but is indicative of the condition.

* Diabetic Statistics, George F. Baker Clinic, prepared by the Statistical Bureau of the Metropolitan Life Insurance Company.
† Deaths reported through May 26, 1948.

A REVISION OF DIABETES STATISTICS AND WHAT IT SUGGESTS

The interpretation of diabetes statistics, cheerful as it is from some points of view, is misleading. It is said that diabetic patients live nearly three times as long now as did diabetic patients in the first fifteen years of this century, fourteen and four-tenths years instead of four and nine-tenths years from the onset of diabetes. That is far below the mark. First of all, this statement is based wholly on fatal cases and takes no account of living diabetic patients. For each patient with onset of disease in childhood who died of the disease (424) in the last fifty years there are 5 alive (2,235). Second, it forces into the diabetes hopper for computing averages all those older diabetic patients who were 62 years or more at onset whose life expectancy without diabetes is fourteen years or less. Moreover, the duration of life in the fatal cases in the first decade of life has now risen to 19.1 years, with similar increases for older persons (table 1). The duration of life of the older diabetic person advances, though far more slowly. In another fashion the improvement is shown by observing the falling percentage of deaths in the first five years of diabetes and the rising percentage for persons who have survived twenty or more years (tables 2 and 3).

Mr. Marks of the Statistical Department of the Metropolitan Life Insurance Company has not yet computed the present expectancy of life of diabetic patients for 1948, but two years ago it was approximately three-fourths that of the general population instead of two-thirds some seven years before. Therefore, in the interpretation of diabetic statistics, one should consider them by decades, with attention to life expectancy as well as fatalities.

CONTINUOUS SUPERVISION OF DIABETICS

More than 60 per cent (13.8 and 24.5) of my diabetic patients die between the fifth and twentieth year of their diabetes. This demonstrates where the present attack on the disease should be centered, namely, on those diabetic patients who have passed the early stage of the disease. In other words, we must follow up patients more carefully. They must be kept under continual observation. They must be asked to come back every three, four or six months. May I illustrate the necessity for this by a recent chance observation? On one floor of the New England Deaconess Hospital there were 27 diabetic patients. Their average duration of the disease was nine years. Excluding 1 child and 7 adults whose diabetes could be proved to have existed only one year, but which, from their original weights and their present status, undoubtedly must have lasted far longer, the average duration was thirteen years, and in this group the cause of admission was almost without exception gross lack of care. With ward hospital rates at least $9 a day and the shortage of nurses, think of the needless waste of money and of nursing time. This is what strikes me as the pressing problem in diabetes today—the necessity for a more careful follow-up of each patient. One must exercise care in the treatment of the diabetic patient during the entire course of his disease, when it begins and when it ends. What a future the doctor can have who will follow up his cases every few months. It is not so much to specify the frequency of the visits—whether every two, three, four or six months—as for the patient and the doctor to be in partnership, always in contact, the disease to be controlled and all untoward symptoms and signs noted promptly and rectified. I am not extolling now any particular type of treatment, but I am emphasizing the necessity to control the disease and prevent accidents. The life insurance companies will stimulate this follow-up procedure, because when a diabetic person wishes insurance, the physician will be asked how often his condition is checked.

Table 2.—*Length of Life After Onset of Diabetes; 9,554 Deceased Patients**

| | Percentage of Total | |
|---|---|---|
| | Less Than 5 Years | 20 or More Years |
| Naunyn, 1898-1914 | 66.8 | 1.8 |
| Allen, 1914-1922 | 53.9 | 3.1 |
| Banting, early, 1922 | 40.7 | 4.8 |
| | 22.8 | 9.4 |
| | 15.7 | 14.4 |
| | 13.8 | 24.5 |

* Prepared by the Statistical Bureau of the Metropolitan Life Insurance Company.
† Deaths reported through May 26, 1948.

The diabetic patient's office visit should never be perfunctory and never for diabetes alone. It should include discussion of insulin, diet, exercise and rest, and a complete health examination, and except for the few frequent visits at onset and inauguration of treatment or rectification of some special intercurrent complication, all the clothes should come off. The examination should be so detailed that the patient can see that he is getting his money's worth—treatment of his diabetes and a health examination besides. Only 1.9 per cent of my patients now die of coma, and therefore, when they come to the office, the physician should protect them against the 98 per cent other causes.

### THE MILLION UNKNOWN DIABETIC PERSONS

The Oxford Diabetes Survey[7] demonstrated that for the known diabetic person there was an unknown. How shall the million unknown diabetic persons in the country be recognized? My answer is simple and involves little expense. It is up to the doctor and the diabetic person. The unknown diabetic person is no elusive creature. He is the relative of a diabetic person, and more than 80 per cent of diabetic persons are fat. To find him or her all that is required is that 140,000 doctors examine the blood and urine of the relatives of their diabetic patients, especially those who are fat and above the age of 25 years, or have their patients screen the relatives by doing urine tests. This narrows the problem. Only one third of the people in the country are over 40, and yet persons above 40 constitute two thirds of the diabetic patients. It is infinitely cheaper to get that message across to the doctors and the patients than to attempt a multitude of expensive surveys, now that the United States Public Health Service has so beautifully blazed the way. If we doctors fail to do it, state medicine will, and the doctors will lose the fees and be taxed to pay the bill. In this search, already the specialists are aiding internists by detecting cases and dentists and chiropodists are constantly discovering suspects.

† Deaths reported through May 26, 1948.

Many diabetic surveys, however, are still needed. We should know the percentage of diabetes among blind persons and among those with cataracts. In Arizona I found diabetes as frequent among the Indians as in the rest of the population, when one considered their sex, age, accessibility to medical attention and statistical tabulation. How does the incidence of diabetes in Iceland with its divergent diet and hours of daylight compare with that in the United States when evaluated under similar conditions and similar methods? What is the incidence of diabetes in Guam, where arteriosclerosis is said to be almost nonexistent? We know that diabetes differs little in frequency between the Negroes and whites, if the blood and urine are tested. How is it in China? There are certainly diabetic Chinese in the United States. I see a large number. There were only 74,954 Chinese in the country in 1930, and in 1940 there were 2,513 in Massachusetts and 1,380 in Boston. By a survey of these it should be easy to learn how many are diabetic, and the data thus acquired could be applied to China as a whole.

In any study of the incidence of diabetes the data in table 4, compiled by the Statistical Department of the Metropolitan Life Insurance Company from the house to house canvass in the National Health Survey, 1935-1936,[8] should be borne in mind. Everyone concedes its inaccuracies, because it is not based on chemical analyses of urine and blood but on oral reports; yet until a better report is forthcoming, it shows that the age and sex of the population surveyed are important factors for a correct interpretation.

### DIET

Great advances have been and are being made. Few physicians advocate less than 150 Gm. of carbohydrate in twenty-four hours, and one would administer insulin if such an amount could not be tolerated without the occurrence of glycosuria and hyperglycemia. No one recommends that a diabetic person should become obese. The disease developed in Houssay's[9] toads, which were made susceptible to diabetes with alloxan, if all their food was given at one meal, but the diabetes did not develop in the toads when the same quantity of food was spread throughout the twenty-four hours. Groen's[10] normal dogs died if fed fat bacon exclusively. There is room here for many dietary modifications, and time will show which is the best.

### INSULIN

Insulin has made possible the improvement in diabetic treatment.[11] The 10 year old children in 1897-1913 had a mortality rate of 824 per thousand in a year, and this has dropped in 1939-1945 by 99 per cent. The 30 year old patients had a yearly mortality rate of 359 per thousand, and this has fallen by 97 per cent. Even the 50 year old and 60 year old groups show reduction in death rate of 75 per cent and 72 per cent, respectively. With such startling improvement in the quarter century since insulin was discovered, one wonders why it is not used more. I believe that at least 85 per cent of the diabetic patients at the New England Deaconess Hospital take it. Over and over again in our medical-surgical rounds at the hospital on Monday mornings, promptly at 8 a. m. (to which all are invited), it is asked, "Must a diabetic patient get coma or gangrene or become blind or pregnant, get a stroke or have an insurance examination before his or her diabetes is recognized and insulin started?"

TABLE 4.—*Ratio of Diabetes in the Population**

| Age | Male Patients | Female Patients |
|---|---|---|
| 0-14 | 1:2500 | 1:2500 |

| 65 and over | 1: 70 | 1: 45 |

* The magnitude of the Chronic Disease Problem in the United States, Division of Public Health Methods, National Institute of Health, United States Public Health Service, 1938.

Every few years there is an improvement in insulin, and surely all possible improvements have not yet been made. I have high hopes for the new modified protamine zinc insulin (NPH50) which we shall test in our diabetic camps this summer, because it is supposed to combine in one bottle the advantages of a short-acting and long-acting insulin. At present patients with diabetes of long duration are apt to take the regular insulin and protamine zinc insulin by separate injection in the morning and, if the condition is severe, often 4, 6 or 8 units before the evening meal.

Reactions should be avoided; but if a patient occasionally does not have a sign of a reaction, would that indicate that his diabetes is well controlled? For some patients 3 to 5 Gm. of carbohydrate hourly is essential for safety, and it is easily supplemented with protein and fat. For those driving an automobile food should be taken every two hours, and even though the patient may not be driving a 10 ton truck he should act as if he had that responsibility.

Would not every doctor keep his patient sugar free the entire twenty-four hours if he could do so without exposure to an insulin reaction? I tremble for the patient who is told that he may omit insulin. Before I advise that a patient omit it in the future, I shall insist that he sign his name to a statement that he has been advised, as long as he lives, to test his urine after a meal and have a blood sugar test every three months.

## DIABETIC COMA

At the Massachusetts General Hospital, Dr. Reed Harwood told me recently, there has been no death in the last 41 cases of diabetic coma. At the New England Deaconess Hospital on our service we have just completed a series of 92 successive cases also without a death, making a total in the two institutions of 133 cases without fatality. There is no boasting in these results. They are simply facts, and the reasons are plain. In our group the results are in large measure due to the cooperation of physicians within 50 miles of the hospital who in nearly half of a large series of patients with coma administered insulin just before the patient was put into the ambulance for a quick ride to the hospital. We know that our patients, in a previous but also recent survey, receiving practically the same amount of insulin in three hours as they did in twelve hours formerly, showed a mortality rate of 1.4 instead of 14 per cent. Liberal doses of insulin, promptly administered, prevent deaths from coma. We consider diabetic coma to be a grave emergency; the resources of the laboratory and the staff, young and old, are marshaled for its relief.

Our method of treatment of diabetic coma is herein outlined:

## TREATMENT OF DIABETIC COMA

### First Hour After Admission

*Assign special nurse, experienced in coma treatment, for the first few hours.*

#### LABORATORY

1. *Urine.*—Examine for sugar, diacetic acid, albumin, coma casts and pyuria. Catheterize if necessary.

2. *Blood.*—Test for sugar and carbon dioxide content, with emergency report inside the hour. White blood cell count and nonprotein nitrogen also of value.

3. *Search for Complications*
   A. History to explain cause of coma
   B. Physical examination, noting particularly:
      (*a*) State of consciousness, type of respiration, pulse rate, blood pressure and rectal temperature
      (*b*) Look for soft eyeballs, dry tongue, dilated stomach, cold and mottled skin and impacted rectum.

4. *Insulin.*—100 units of crystalline insulin subcutaneously at once for adults, if blood sugar exceeds 300 mg. per 100 cc. and if the blood carbon dioxide content is 9 millimols per liter (20 volumes per hundred) or less. The dose would be proportionately less in cases of recent onset of diabetes or in young children. In cases with blood sugar between 600 and 1,000 mg., give 200 units additional, and with blood sugar over 1,000 mg., give 300 units additional. In patients in circulatory collapse, give preliminary additional doses of insulin intravenously.

5. *Gastric Lavage.*—Use large tube, aspirate completely and wash stomach with warm water with greatest care.

6. *Sodium Chloride.*—Give 2,000 cc. of isotonic sodium chloride solution intravenously and repeat if indicated by dehydration and blood pressure below 90 mm. of mercury. Avoid too rapid administration, especially in older patients.

7. *Warmth.*—Keep patient warm, yet avoid burns, as from hot water bottle.

### Second to Sixth Hour

Occasionally the gravity of the condition necessitates repetition of *first hour's total insulin in the second hour.*

8. *Tests.*—Repeat blood sugar and carbon dioxide determinations after three hours. For rising blood sugar give insulin 50 to 200 units, according to physician's judgment of prognosis.

9. *Fluids by Mouth.*—As soon as tolerated give 100 to 120 cc. per hour of broth, ginger ale, orange juice, tea or coffee, to be sipped by patient or spooned by nurse. If nausea and vomiting recur, withhold fluids orally for twelve hours (lavage stomach again if indicated) and then resume.

10. *Soft Food.*—Soft or liquid food such as oatmeal gruel, orange juice or milk diluted half and half with lime water, not to exceed 10 Gm. carbohydrate per hour.

11. *Enema.*—For cleansing and to relieve abdominal distension.

12. *Blood Pressure, Pulse and Temperature.*—Record blood pressure, pulse and temperature; note signs of improvement or the reverse.

13. *Urinalysis.*—Urinalysis for sugar and diacetic acid every hour. Record volumes.

### Sixth to Twenty-Fourth Hour

14. *Tests.*—Repeat blood sugar and carbon dioxide determinations and give insulin, 50 to 200 units, if blood sugar and carbon dioxide levels are not improving.

Insulin (crystalline) may now be given according to results of urine tests every one to four hours if fall in blood sugar has been satisfactory.

| If test is— | Red | Orange | Yellow | Green | Blue | |
|---|---|---|---|---|---|---|
| Give— | 20 | 16 | 12 | 0 | 0 | units |

15. *Urinary Output.*—Observe this closely and note with alarm any sign of anuria. Treat with 1,500 cc. of isotonic sodium chloride solution intravenously if shock is persisting. Repeat as necessary. For anuria, associated with hypochloremia, give 50 cc. of 10 per cent sodium chloride solution intravenously. Never give hypertonic dextrose solution to promote diuresis. Beware of producing excessive diuresis with consequent loss of base, especially of potassium.

### Second Day

16. *Soft Food.*—Diet: carbohydrate 100 to 150 Gm., protein 50 Gm. and fat 50 Gm.

17. *Protamine Zinc Insulin.*—Protamine zinc insulin should be given, supplemented by crystalline insulin in small to moderate doses before meals, as indicated by results of blood sugar and urine tests.

### Third Day

18. *Diet.*—Patient should gradually return to the standard diabetic diet for age and weight with carbohydrate 150 to 200 Gm., protein 60 to 100 Gm. and fat 60 to 120 Gm. daily.

As there have been no deaths in the last 92 cases, I see no reason to change the method of treatment. Particularly I would call attention to its simplicity, the absence of use of dextrose or alkalis. Thus far the employment of potassium has not been necessary, and, in fact, until patients with diabetic coma treated without dextrose have been shown to need it, I hesitate to give advice for its use except in those clinics where quick tests for potassium are available.

### TRANSMETATARSAL OPERATIONS

Several lessons are to be learned from the unpublished report of my colleague, Howard F. Root,[12] on one hundred and seventy transmetatarsal operations on our diabetic patients apart from the excellent results which the surgeons Drs. Leland and John McKittrick, Dr. Theodore Pratt and Dr. Clifford Franseen have obtained. Six out of seven operations have been successful, and in many of the cases this type of operation has saved an amputation above the knee and at the same time produced a useful foot. The duration of the diabetes was nine years in the male patients between 51 and 60 years of age and fifteen years for the female patients between 71 and 80 years. The duration was ten years in the cases of successful treatment and fourteen years in the cases in which treatment failed. In the 6 patients under 51 years of age the average duration was fourteen years. Dr. Root concluded, "1. Mildness of the diabetes is no protection against gangrene. 2. Instruction in the care of minor lesions must be repeated. Do not walk on a sore toe. 3. The insensitive foot is the most dangerous and least resistant to infection. Lack of pain leads to procrastination eventually preventing the use of conservative treatment and conservative operation."

This group of cases stands out as composed of cases of mild diabetes of long duration in patients who had formerly been extremely obese. In 22 cases the average maximum weight was 245 pounds (111 Kg.); in 52, 208 pounds (94 Kg.), and in 50, 170 pounds (77 Kg.). In only 4 cases was the maximum weight under 150 pounds (68 Kg.). Only 13 of the patients had been on a measured diet and even on that for a small part of their diabetic lives. Likewise, there was a comparatively long period during which diabetes had existed without treatment by means of insulin. Glycosuria and hyperglycemia were not only present at admission but had probably been present long before the occurrence and development of the lesion which brought about admission to the hospital.

An average of 31 units of insulin as a maximum and 17 at discharge and 164 Gm. of carbohydrate with 1,764 calories were given the 111 patients for whom treatment was successful and 48 and 24 units, respectively, and 159 Gm. of carbohydrate and 1,652 calories to the 22 patients for whom treatment failed.

### CANCER

What recently gave me satisfaction in a review of a series of cases of cancer among our diabetic patients was the number who were either cured by operation or lived so long that death finally occurred from another cause. Perhaps statisticians of cancer mortality are observing this right along. It is what one ought to expect. Diabetic patients are constantly undergoing health examinations, and their doctors, therefore, should diagnose their cancers early. I hope that this avenue of investigation will appeal to the cancer seekers and that they will see the advantage of concentrating on diabetic patients so as to learn how treatment will be most efficacious in the earliest stages and from diabetic patients get cheer for other cancer sufferers.

Cancer as a cause of death has increased from 1.5 per cent in 1898-1914 to 8.6 per cent in 1944-1948. It is little more than half the cancer mortality rate, 15.8, for white persons ages 45 and over in the United States, but, as in nondiabetic persons, stands next to arteriosclerosis as a cause of death. Undoubtedly it would be higher than 8.6 per cent if diabetic persons lived longer.

### EDUCATION AND HOSPITAL CARE

Education of the diabetic person is a *sine qua non* in any method of treatment. Doctors cannot take over another million diabetic persons for instruction, however, unless they revise their methods. Most of the cases are office cases, and the time taken to explain all the ins and outs of diabetes is too great. We doctors must bring into our offices helpers whose medical training has been far less expensive and time-consuming than our own. Nurses and dietitians are not available at the prices the patients are able to pay. Therefore, we must turn to nurses' aides of one description or another. Instruction the patient must have.

Similarly we must have cheaper accommodations for those ambulatory patients who need introduction to diabetic treatment or its revision from time to time. With rising hospital costs, hospitals should grasp the point that systematization and a better classification of their admissions would lower the costs both for the patient and the public who voluntarily or by taxation are saddled with the bills. I expect to see this idea spread rapidly with mounting hospital deficits and decreasing revenues from community drives.

There are at least 15,000 diabetic children in the United States and 100,000 living persons the onset of whose diabetes was in childhood. Yet (shame on us) as yet only 1 child in 20 has an opportunity to go to a diabetes camp, where children get more benefit from their stay and are better treated than in a hospital ward.

### DIABETES FUNDS

In the talks I give my diabetic patients, I always tell them to see to it that the hospital nearest them is equipped to care for them in an emergency. A blood sugar report for the unconscious patient is just as valuable to him on Sunday afternoon as on any week day. The hospital will permit a woman to have a baby and recognize its duty to care for her and it on any day of the week, and the same rule should hold for an urgent diabetic admission.

The diabetic person having provided for his own safety, then I believe it is to his advantage to contribute to the furtherance of diabetic treatment and the promotion of research. Of course, if his own community is not enterprising enough to have a diabetes fund, how can I help telling about our own? A diabetic who will give a dollar a year for treatment and research in diabetes will be a better patient, and there are 1,000,000 known diabetic patients in the country. Finally, $1 from 1,000 diabetic persons is better than $1,000 from 1, because the thousand dollar donor may die, but most of the 1,000 diabetic dollar donors will live long and continue to manifest an interest in their disease.

### BLOOD SUGAR

A $5 charge for a blood sugar test is a dreadful deterrent to good treatment. One may not need many tests, but occasionally they are most revealing and reassuring. If the blood sugar test is combined with a medical visit and advice, that, of course, is a different matter. I think that laboratories should sell blood sugar books and blood sugar tests wholesale or establish bargain blood sugar test days or hours, so that patients are stimulated, encouraged and even enticed into knowing the more exact status of their diabetes—in fact, to better its control. The controlled diabetic person escapes diabetic coma and avoids many needless and embarrassing pitfalls.

### DIABETES AND EPILEPSY

In a recent review course of instruction in neurology which I was taking, I was much impressed by the analogies between diabetes and epilepsy. Indeed, epilepsy is constantly presenting itself in the differential diagnosis when an insulin reaction occurs, and, indeed, the incidence of epilepsy is greater in diabetic than in nondiabetic persons. It is said that there are 1,000,000 known diabetic persons and estimated that there are 1,000,000 unknown. The guess is made that there are 800,000 known epileptic persons and a corresponding number whose condition is undiagnosed. Treatment of epilepsy has notably improved with the use of phenobarbital diphenylhydantoin sodium ("dilantin") and trimethadione ("tridione"), but the specialists say that following up the treatment of the disease in routine visits yields astonishingly better results than simply dispensing the medication. Good old-fashioned doctoring of the whole condition of the patient and not of the episodes of grand mal alone, I understand, may lessen the latter toward the vanishing point. Nowadays I suppose that this would be called psychosomatic medicine, but truly that should always form a part of the day's work for the doctor. It is sort of thrown in "without money and without price." The family doctor is the doctor *par excellence* for epileptic and diabetic patients, and he should be made to feel it and help in the technics of treatment. In fact, any student who thinks that he wants to become a diabetes specialist should remember that today only 1.9 per cent of the diabetic patients die of their disease and therefore he must be up to date in 98.1 per cent general medicine if he expects to give his patients adequate care.

### PREGNANCY

Diabetic women may want to become pregnant, and if their husbands are nondiabetic and come from nondiabetic or only slightly diabetic families we have no right to interfere. But all will agree that they must keep under close supervision. Moreover, if, as Dr. Priscilla White [5] has shown, only 1 in 4 or 5 with calcified pelvic arteries can give birth to a living and healthy infant, it is only fair that the mother and father should be warned in advance of conception.

### URIC ACID DIABETES

I have always believed in the importance of alloxan diabetes as a great step forward in the elucidation of the disease. Alloxan can be made out of uric acid, which we all have in abundance. Bailey, Bailey and Leech [13] in our laboratory have shown that when alloxan is given to a rabbit the level of glutathione, another component of the body, falls. The two appeared antagonistic. By giving glutathione they hoped to offset the diabetogenic action of alloxan. This they were unable to do, but Lazarow [14] of Cleveland accomplished it. Naturally, therefore, I was greatly pleased to see the announcement of Dr. Mervyn Griffiths [15] of Canberra, Australia. He reported that blood glutathione can be reduced to very low levels by feeding rabbits a diet deficient in cystine and methionine. After six or seven weeks of such a diet the glutathione is at approximately one half its previous level. If uric acid is then injected intraperitoneally hyperglycemia and glycosuria develop in the rabbit, which last for five or six days, and this he terms uric acid diabetes. Control rabbits given uric acid failed to show these changes when the blood glutathione was not first decreased. The pathologic aspect of uric acid diabetes has not yet been reported. To this brief publication, only two pages in length, I attach great significance, even though it is based on experiments with only 4 rabbits. All of us have uric acid and glutathione in our bodies. Suppose that diabetic patients had adequate supplies of glutathione, would their disease advance less rapidly; could we in this way protect their relatives? The possibilities suggested by this announcement are unique, provocative and stimulating. Even if it is not glutathione, there might be some other chemical which could be employed which would deter some substance like uric acid from yielding alloxan or a product akin to it. Hitherto to escape diabetes one had to shun a diabetic heredity or obesity, but now an entirely new avenue for investigation is opened. Would it not be wonderful if something should come of it? At any rate, I predict that the treatment and methods of prevention of diabetes will change radically in the next few years. I believe that we are on the threshold of a new discovery, and I hope to live to see it.

## ABSTRACT OF DISCUSSION

**Dr. W. Wallace Dyer**, *Philadelphia*: Over the years, we have looked to Dr. Joslin and his group to lead the way in the furtherance of the diabetic patient's welfare. As the physiologist, the biochemist, the biologist and allied scientists have prepared the missiles, Dr. Joslin has helped set our sights, and today's communication is no exception. A million new diabetic persons to be discovered and started on treatment! This is certainly a challenge. I share Dr. Joslin's restricted optimism of avoidance of premature arteriosclerotic change in some of the long term juvenile diabetic patients. I cannot give a report as yet, but the department of ophthalmology at the University of Pennsylvania is engaged in reviewing cases of diabetes of twenty to twenty-five years' duration. I can only say now that my personal impression is that for the most part those patients who have been best controlled over the years have the least vascular damage. Until more convincing evidence is available than has been presented hitherto, I shall attempt in each patient to obtain normal blood sugar values throughout the twenty-four hours and to maintain a twenty-four hour negative reaction for sugar in the urine. Obviously, I do not secure this type of control in all of my patients, but an occasional failure due to my own inadequacies or the patient's lack of cooperation is no excuse for not trying. I am afraid that I cannot agree with Dr. Joslin that coma deaths have approached the vanishing point. That is not my experience on Dr. Dillon's service at the Philadelphia General Hospital. In my conversation with many of you during your visits to the booth, I gather that you too are still having coma deaths and they continue to represent a sizable part of your total diabetic mortality. No doubt, some of these deaths can be prevented by earlier diagnosis and earlier adequate treatment. In the severe coma patient especially, adequate treatment now includes administration of potassium controlled by the electrocardiogram as described by Bellet and Nadler recently in Philadelphia. The fact that in Dr. Joslin's cases 60 per cent of the deaths occur in the cases in which the diabetes has been of five to twenty years' duration emphasizes a point which we are all too likely to forget, namely, the diabetic needs continuous follow-up and supervision. It has been my experience that the new diabetic patient starts off with a great deal of enthusiasm and honest desire to maintain his diabetic regimen. As time moves on, he slips a little and gradually strays far afield. If the physician is present constantly to keep him on the track after the initial enthusiasm wears off, the broom will continue to sweep clean after it is no longer new.

[15] Griffiths, M.: Uric Acid Diabetes, J. Biol. Chem. **172**: 853-854, 1948.

Dr. Henry T. Ricketts, Chicago: Dr. Joslin suggested that efforts to discover the cause of arteriosclerosis in diabetes may provide clues to the mystery of arteriosclerosis in general. While this may prove to be true, one should bear in mind that there are certain important differences between the total vascular picture in diabetes and that in senescence. Both conditions lead to changes in the arteries, but only diabetes damages the capillaries of the retina and the kidneys, likewise the retinal veins, in an almost specific way. Although one may produce sclerosis of the arteries in animals, as for example by feeding cholesterol, the peculiarly diabetic lesions of the capillaries and veins have not been produced by any experimental method. Dr. Joslin also referred to several papers describing the high incidence of serious vascular complications in young or middle-aged diabetic persons, originally "juvenile" diabetic persons, who have had their disease for twenty to twenty-five years. It is often stated that such complications occur regardless of the degree of control of glycosuria. This statement is difficult to support with factual evidence, for one cannot know with certainty the day to day level of control in patients whom one sees only once in one to six months, even though on the days one does seen them all seems well. The fact that Dr. Priscilla White has found vascular lesions in 93 per cent of her juvenile cases of long standing should in itself arouse our suspicion that poor control is a factor; it is notorious that the vast majority of these young unstable patients cannot be kept free of glycosuria for any considerable period of time. The future may prove that hyperglycemia and hyperlipemia play no role in these degenerative phenomena, but the evidence available today does not justify our discarding the possibility that these factors are important, and we should treat our patients accordingly.

Dr. Frederick M. Allen, New York: The maintenance of a normal level of blood sugar, which I was first to advocate, has been made easier by the discovery of insulin. By this method diabetic complications are preventable. For "furtherance of diabetic treatment," nobody typifies better than Dr. Joslin the value of individual personality, inspiration and initiative, in contrast to regimentation. Clinical evils have resulted when a college, which is necessarily a self-contained oligarchy, oversteps its educational function by usurping control of medical services for large populations. Diabetes furnishes one test of whether advances occur because of oligarchy or in spite of it. From a review of the overbalanced fat and carbohydrate diets, the recent deadly doctrine of leaving diabetes uncontrolled and the lax intermediate standards, it appears that the large institutions have been inferior not only to Joslin's clinic but to other smaller clinics or private practitioners in demonstrating successful prolonged control. In the related field of hypertension, which enters as a complication in many cases, especially among elderly diabetic patients, the oligarchic suppression of the treatment by salt restriction has likewise been responsible for a large unnecessary mortality rate during a quarter-century. Physicians should test for themselves the validity of the principle in both diseases; namely, that thorough physiologic control, especially in early stages, averts the later hopeless consequences.

Dr. Joslin: I appreciate all the words of those who have discussed the paper. We can take to heart what each one has said. The general unanimity about controlling diabetes, I think, is strengthened. We look to Dr. Ricketts for further studies in arteriosclerosis and to Dr. Dyer, because in Philadelphia now so many investigations of a new nature are going on in diabetic trauma. We are particularly fortunate, I think, in our coma cases. Our patients are certainly not as bad as those who come to many general hospitals. We know that, but I think that it is significant that at the Massachusetts General Hospital improvement has recently been striking. I would welcome hearing of patients free from degenerative vascular lesions after twenty-five years of diabetes, because, if we can find them and then see how they have lived, we could learn how to protect others. A question was put to me about the special insulin. I think that I will not discuss that, because all insulins are good. We could use any insulin. I treated diabetes for twenty-five years without it. I know what diabetes is without it and how thankful I would be for any insulin. The point is to use the insulin which you have and use it wisely and control the disease to the best of your ability.

---

# OFFICIAL SYRINGE OF THE AMERICAN DIABETES ASSOCIATION

LESTER J. PALMER, M.D.
Seattle
and
FRANKLIN B. PECK, M.D.
Indianapolis

In 1943 the Council of the American Diabetes Association appointed the Committee for Standardization of the Insulin Syringe. The need for this action by the Council arose from the following facts. After the discovery of insulin in 1921, and its use by the profession in the treatment of diabetes became general in 1923, many different types of syringes for the administration of insulin gradually appeared on the market. Each of these syringes was considered by the originator of each of the various designs to have certain advantages over any of those previously available. The number of different types increased until literally dozens of different models were being manufactured.

In general, the different syringes were of two types—those which carried graduations indicating various fractions of a cubic centimeter and those which carried graduations indicating the number of units.

Early in its history insulin was marketed in dilutions as low as 5 units per cubic centimeter, and later as high as 100 units per cubic centimeter. Those syringes which carried scales indicating fractions of a cubic centimeter used fractions varying from $\frac{1}{100}$ to $\frac{1}{4}$ cc. The most commonly used fraction was $\frac{1}{10}$ cc. The capacity of the syringes with this type of scale was most often 1 cc., but some had a 1.5 cc. and some a 2 cc. capacity. Some of these syringes showed the fractionation markings numbered numerically, and on some syringes the graduations of the scale were indicated in fractions of a cubic centimeter. These various types of scales were considered to have the advantage of being usable for whatever strength of insulin solution was being currently employed.

The other type of scale or marking indicated the dosage in terms of units. It was at first considered necessary to have a syringe scaled for each different strength of insulin, so that for a time when 10, 20 and 40 U. S. P. units per cubic centimeter were the available strengths of insulin, there were three different syringes with this type of scale on the market. It then seemed to be more economical to place several scales for the different strengths of insulin on the same syringe. As a result of this policy, there were syringes with as many as three different scales on each syringe. Later, when 80 unit insulin became available, and 10 unit insulin was withdrawn from the market, the two most commonly seen syringes of this type carried two scales on each syringe—either scales for 20 and 40 U. S. P. units per cubic centimeter or a second combination, scales for 40 and 80 U. S. P. units per cubic centimeter.

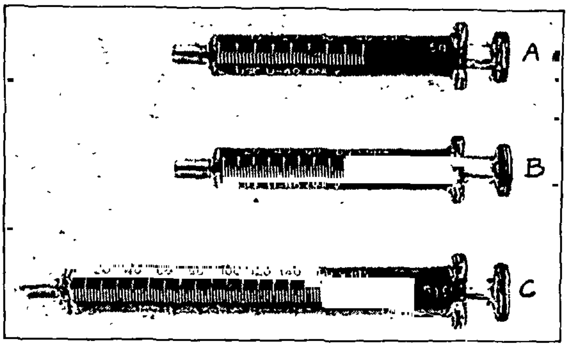
Various modifications in the kind and color of glass, such as green glass and blue plungers, were employed.

---

The Committee of the American Diabetes Association for Standardization of the Insulin Syringe.

In addition to the short standard length (usually 3 inches [7.6 cm.]) of syringe barrel, the longer, slender type of barrel was manufactured, similar in dimension to the "tuberculin" syringe.

This multitude of different kinds of syringes employed in measuring the dosage and in the administration of insulin was steadily increasing in numbers through applied individual ingenuity, when the Committee for Standardization of the Insulin Syringe was created in 1943. Such action was considered necessary by the Council of the American Diabetes Association because of tremendous confusion among the users of insulin regarding the measurement of prescribed insulin dosage. A few examples of such confusion will be cited. A patient employing a syringe with 1/10 cc. graduations, the graduations being numbered from 1 to 10, would frequently state his dose of insulin in units as the number of the fractionation mark, regardless of the strength of insulin being employed, so that 5 units might mean anything from 5 units to 40 units of insulin. When the scale was marked in fractions of a cubic centimeter, the patient often spoke of his dosage in terms of fractions instead of in units and frequently could not recall just what strength of insulin he used. Having left the insulin, and frequently the syringe, at home, neither the doctor nor the patient could be certain what dosage the patient was employing at the time of the visit, and the doctor would be at a loss to indicate to the patient the dose he desired to prescribe. Another frequent example of the confusion existing among those patients using a syringe on which the scale indicated units of more than one concentration of insulin arose from the common practice of patient's measuring insulin of 40 U. S. P. units per cubic centimeter on a 20 or an 80 unit scale, thus stating his dose of insulin to be twice, or half, the actual dose employed. Many variations of this error were possible. These are a few examples of the many errors patients were making and are still making, because of the great variety of insulin syringes still available on the market.



Official syringes. Model 1, for 40 unit strength only. The scale is marked in red enamel. Capacity 40 units. Model 2, for 80 unit strength only. The scale is marked in green enamel. Capacity 80 units Model 3, for 80 unit strength only. The scale is marked in green enamel. Capacity 160 units. (Manufacturers may obtain detailed drawings made to scale and typewritten specifications from the office of the American Diabetes Association, 1 Nevins St., Brooklyn 17, N. Y.)

Some physicians, acutely conscious of the many possible errors, attempted to minimize such errors by insisting that the patient bring with him, when visiting his doctor, both his syringe and his bottle of insulin. This gave the physician the opportunity to check under actual observation the dose of insulin being employed by the patient and also to demonstrate to the patient the actual dose of insulin which he prescribed.

Manufacturers were also dissatisfied with the many varieties of insulin syringes that it was necessary for them to create and to detail to the trade. Retail outlets were obliged to attempt to carry in stock a varying but large number of the different kinds of insulin syringes.

Patients taught to use insulin in one diabetes clinic or hospital, or by their personal physician, frequently found it impossible to replace a broken syringe with a similar one, because they were distant from the site of original purchase. They were then obliged to buy a syringe of another type, with which they were not familiar, and to accept the advice of some uninformed clerk or other person as to how to measure the prescribed dose of insulin on a new and unfamiliar syringe. Of course, there were some persons, whose minds were sufficiently mathematical and whose knowledge of the different strengths of insulin solution was adequate, who could compute their dose properly even on a syringe with which they had had no previous experience. The majority of patients, however, were not so mathematically minded, and hence a tremendous amount of confusion resulted.

The clinical results of this confusion led to poor treatment, varying from poor control of the diabetes, or even varying degrees of acidosis, to severe and even dangerous insulin shock.

Sufficient has been said to give the history of the insulin syringe and to emphasize the confusion and dangers arising from the great number of kinds and types of insulin syringes which had appeared on the market by 1943. It is probably safe to say that the number of models has increased considerably during the past five years. The Committee for Standardization of the Insulin Syringe presented on many occasions to the Council of the American Diabetes Association suggestions and recommendations for a standard type of syringe which could receive the approval and endorsement of the American Diabetes Association and thereby be considered "the official insulin syringe." Finally, in June 1947, the details and specifications of "the official insulin syringe," approved and endorsed by the American Diabetes Association, was accepted by the Council.

### DESCRIPTION OF MODELS

There will be three models of the official syringe.

*Model 1.*—Model 1 is to be used for insulin of 40 U. S. P. units per cubic centimeter of any kind (that is, regular insulin, insulin made from zinc, insulin crystals or protamine zinc insulin). It will have only one scale, reading 10, 20, 30 and up to 40 units, with suitable subdivisions, and will have a total capacity of 1 cc., or 40 units. The numerals and division lines on the scale will appear in red enamel, corresponding to the red color scheme officially adopted for the labeling and identification of all kinds of 40 unit strength insulin. This syringe should not be used for any strength of insulin except 40 units. This last designation will appear on the syringe.

*Model 2.*—Model 2 is to be used for 80 unit strength insulin of any kind. It will have only one scale, reading 20, 40, 60 and up to 80 units, with suitable subdivisions, and will have a total capacity of 1 cc., or 80 units. The numerals and division lines on the scale will appear in green enamel, corresponding to the green color scheme used to identify all kinds of 80 unit strength insulin. This syringe should not be used for any strength of insulin except 80 U. S. P. units per cubic centimeter. This latter designation will appear on the syringe.

*Model 3.*—Model 3 may be used for the measurement of 80 unit strength insulin of any kind, but is designed particularly for patients who need to use more than 80 units of insulin. It will have only one scale, reading 20, 40, 60, 80 and so forth, up to a total of 160 units and will have a total capacity of 2 cc., or 160 units. The numerals and division lines on the scale will appear in green enamel. This syringe should be used only for measuring a dose of 80 unit strength insulin and is necessary only when the dose of insulin exceeds 80 units. The syringes of 1 cc. capacity will have an approximate over-all measurement of 3 inches (7.6 cm.). The one syringe of 2 cc. capacity will have an over-all measurement of a little over 4 inches (over 10 cm.). Some manufacturers may choose to create official syringes which are more slender and hence longer than indicated herein. However, to be official the designated scale, the designated capacity and the color scheme must conform to the aforementioned specifications.

The label on the box containing the syringe is described as follows: Each syringe will be packaged separately in an appropriate box. The paper label on the outside of the box will carry the designation of the name of the manufacturer of the syringe along with the other data. The designation "For use with insulin of 40 unit strength only" will appear in red ink on the label on the box for the 40 unit strength syringe, and the designation "For use with insulin of 80 unit strength only" will appear in green ink on the label on the box for the 80 unit strength syringe. On the labels on the boxes containing any of these approved syringes which meet these requirements regarding the color and scale markings will appear this statement, "The enclosed syringe has a simplified scale which has been approved by the American Diabetes Association." By means of this description and by giving attention to the label on the box containing the syringe and the nature of the scale, a diabetic person should be able to obtain this officially approved insulin syringe by asking for it by name at any drug store where he seeks to make a purchase.

It is the sincere hope of the American Diabetes Association (1) that manufacturers of syringes for the administration of insulin will welcome this official syringe and will as rapidly as practical eliminate from their lines all other "insulin syringes" and restrict their production to this "official insulin syringe," (2) that manufacturers will publicize and promote to their retail outlets the advantages of this new syringe and its endorsement by the American Diabetes Association, (3) that the National Retail and Wholesale Druggists Associations, and their subsidiary state, district and other territorial organizations, will promote to insulin users this syringe to the exclusion of all other types and kinds of insulin syringes, (4) that teaching diabetes clinics and hospitals and all individual physicians will support the endorsement by the American Diabetes Association of this new insulin syringe by employing only this official syringe in teaching new users of insulin and will as rapidly as practical change the syringe used by persons under their direction to the official insulin syringe.

It is sincerely believed that such a cooperative attitude on the part of all those concerned with this problem will present to the diabetic public of America a united attitude and thereby cause much of the confusion and danger of the past to disappear.

# RELATIONSHIP OF THE ANESTHESIOLOGIST TO THE HOSPITAL

JAMES RAGLAN MILLER, M.D.
*Hartford, Conn.*

In opera it is customary for the composer to begin with an overture. Though it appears first, this overture is written last, for it serves not only to allow the audience to get comfortably seated, but it gives a preview of what is to come and an acquaintance with leitmotifs which thereafter can be heard with critical appraisal. I am going to imitate this method and tell immediately what is on my mind.

1. The anesthesiologist should be a member of the professional staff, and his relations to the hospital ideally should be on the same footing as other members of the staff.

2. If his income is in any way regulated by the hospital management, it should be with the advice and consent of a staff committee of senior physicians for which I suggest the name "prudential committee."

I hold that such a prudential committee should pass on all fiscal relationships between physician and hospital when income is derived from other than the customary fees. I suggest the word prudential because it is new in the hospital staff vocabulary.

The meaning of prudential which appeals to me is that given in Webster's Dictionary: "watchful of one's own interest." I would reject the connotation of selfishness and emphasize the meaning, also found in Webster, "sane and temperate judgement, and wisdom that conduces to moral virtue." Such a committee to be useful should be (1) senior in age but still active, (2) small in number, not more than three, and (3) trusted alike by staff and management. The best the staff has to offer is none too good for this job.

We need both principles and mechanisms. Principles must be discussed at the highest levels in the councils of our national organizations. Mechanisms must be perfected and put into action locally. It is as foolish to expect Chicago to solve all medical problems as it is to expect all wisdom and direction on political matters to come from Washington, and while I shall discuss principles it is particularly the local mechanism to which I wish to address myself.

I believe that successful adjustment of relations between hospital and staff is so important that it calls for the utmost of wisdom on both sides, and while this function may have been carried on as a part of the duties of a staff executive committee or some such busy arm of the staff, I think that this area of negotiations merits a separate committee.

## HISTORICAL DATA

Up to 1890 few other than physicians administered anesthetics. In 1889 Miss Dinah Graham, a graduate nurse at St. Mary's Hospital, Rochester, Minn., began administering anesthetics under the supervision of Dr. H. W. Stinchfield. Soon thereafter Miss Edith M. Graham joined her. Both of these nurses had other duties, and they were paid by St. Mary's Hospital. In 1893 Miss Alice Magaw succeeded Miss Edith Graham, who had married Dr. Charles H. Mayo. Miss Magaw is thought to be the first nurse to devote her entire attention to anesthesia. She was trained by Dr. Stinchfield and was employed by the Mayos.

---

Dr. John S. Lundy provided the historical data.

Dr. Isabella Herb joined the staff in 1900, and the anesthesia department became a subsection of surgery, composed entirely of nurses. In 1906 Miss Magaw[1] reviewed over 14,000 instances of surgical anesthesia given during the previous twelve years. Dr. John Lundy became head of the section on anesthesiology in 1924. Dr. Ralph M. Tovell began the first fellowship, often called a residency, in 1929.

### MAYO CLINIC SETUP

The section on anesthesiology at the Mayo Clinic is now organized as follows: There are six staff physicians and thirty-one nurse anesthetists on salary, paid by the clinic and not by the hospitals. There are seventeen fellows in training who receive a stipend from the Mayo Foundation for Medical Education and Research of the University of Minnesota. Of these, seven are classed as first assistants and are paid an additional salary by the Mayo Clinic. From the beginning the patient has received one bill for medical and surgical care, including anesthesia. Sometimes extra charges are made by the hospital for unusual drugs, and arrangements for purchase and maintenance of apparatus vary slightly in the different hospitals connected with the clinic.

I have used the development of the service of anesthesiology at the Mayo Clinic, not to give a comprehensive review of what was going on in anesthesiology in the United States during this period, nor to imply in any way that the pattern of the Mayo Clinic can or should fit every situation. That is absurd. The community hospital in my opinion must provide suitable mechanisms for payment of fees for the superior services offered by trained anesthesiologists. I have used the Mayo Clinic experience to emphasize my thesis that the most important element in our present problem is not salaries or fees as such, but rather the control by physicians, by the staff, in this case by the clinic, and not by the hospital. Except in the beginning anesthesia at the Mayo Clinic has been administered and paid for under the control of physicians, not of hospital administrators or their trustees. This is the essential formula for the sound development of the specialty and of its capacity to serve patients.

### SOME CONSIDERATIONS

In training centers, such as university clinics and famous private clinics, young physicians who seek opportunities to develop in a specialty consider three important items: first, the possibility of obtaining a rich clinical experience; second, the opportunity for advancement, and, third, financial reward. It will be a sad day for us all when this order is reversed. It is inevitable that these considerations influence favorably the finances of some institutions, and the temptation is always at hand, as it is in all apprenticeships, that young physicians may be exploited. This is bad enough if one physician is enabled to profit unduly at the expense of another. *It is intolerable if such profits* accrue to nonprofessional persons, or even to nonprofit institutions, to pay for new facilities or to recoup losses in other departments of the institution. Physicians can rely on physicians to maintain quality of medical care even in the face of diminishing returns, but there is apprehension among physicians concerning the apparent eagerness of hospital management to derive profits from medical services in order that it may erase the red ink on their books in the strictly hospital service departments. Deficits should be borne by the community and not by special groups of physicians and their patients.

The problem before us comes into sharpest relief in the middle-sized community hospital, usually staffed by local physicians. Dr. McCuskey has shown that there are lacking 3,000 anesthesiologists to provide only one in each hospital. For the time being, therefore, many a small hospital, if its staff wishes to obtain the services of a trained anesthesiologist, must do so on part time, as they now do in the case of pathologists and roentgenologists. These skills must be extended from the larger institutions to make surgery safer for more difficult surgical risks. Here, certainly, is need for a prudential committee in each hospital.

In the smaller hospitals, busy staff physicians are at serious disadvantage in maintaining leadership in the affairs of the hospital in the face of full time administrators backed by state and national organizations. The argument of hospital management seems to run somewhat as follows, "You physicians have not organized this increasingly complicated medical care field. People are calling for such organization and we in the administrative world are not only able to organize your services but, as a matter of fact, we have already done so to an extent which you hardly realize." There has been no prudential committee to look after the interest of the staff physician.

This problem has received increasing attention by the specialist groups, by hospital associations, by Blue Cross and Blue Shield and by state medical societies. The prudent committee of the House of Delegates of the American Medical Association was empowered to study this problem and the action taken by the House was reported at the Annual Session in Chicago, June 1948. The Judicial Council has been studying anew the Code of Ethics of the Association in the light of present needs, and the problem under discussion is basically involved in that code.

### MASSACHUSETTS COMMITTEE REPORT

The best review that I have seen up to the time of writing was presented on Oct. 1, 1947, to the Council of the Massachusetts Medical Society by a committee, headed by Dr. Leland McKittrick, commissioned to study special services.[2] This committee was composed of representatives of the anesthesiologists, the pathologists, the roentgenologists, the Blue Cross, the Blue Shield, the hospital association and the Massachusetts Medical Society. It made a unanimous report, defining medical and nonmedical "services other than administrative, rendered by a registered physician directly or indirectly to or in behalf of an individual patient for the obtainment and interpretation of data, including consultation and advice, for the diagnosis, treatment and prevention of disease." I refer you to the full report for extension of this definition. This committee made the following recommendations for the establishment of proper relations between physicians and hospitals:

> That the medical costs of hospital care be separated from the nonmedical costs, as can be done by existing and accepted methods of cost-accounting, and that they appear thus separated on the statement submitted to the patient.
>
> That bills for all medical services be rendered in the name of the physician or physicians performing the services.
>
> That a basic principle in the establishment of charges should be that each department be self-supporting. This principle should

---

[2] Report of Committee to Study Special Services, Council of the Massachusetts Medical Society, New England J. Med. **237**: 874 (Dec. 4) 1947.

be so applied that neither the hospital nor the physician rendering the service will exploit the patient or each other.

That fees for medical services collected by the hospital be established by joint action of a representative committee of the staff and the governing body of the hospital and including also the head of the department and the administrator.

That the basis of financial arrangement between hospital and physician may be salary, commission, fees, or such other method as will best meet the local situation, with due regard to the needs of the patient, the community, the hospital and the physician.

The *New England Journal of Medicine* commented on this report in part as follows:[3]

> So long as organized medicine uses its organization for the benefit of the patient and the improvement of its own standards and public relations, well and good. If, however, its collective power should be used, as could easily happen, to protect its members against reasonable, honest and decent competition even from without the profession, it is treading dangerously close to the less attractive paths of trade unionism.

### OTHER EXPERIENCES AND COMMENTS

When the chairman of the Section on Anesthesiology was brought by the administration of the Hartford Hospital to look over his prospective job, all of us who occupied senior positions on the staff were asked to meet him, to look him over and, I suppose, in turn to be looked over by him. He came to us as a member of our senior staff, though his salary was paid by the hospital. In 1936, precedents had not been set by large community hospitals for him to follow. He had no prudential committee to assist him in his financial negotiations, nor has he had such a committee to give him counsel in the years that have followed. Large community hospitals which are thoroughly committed to training of residents in anesthesia have not yet established mechanisms which might be used as a guide for organization of such departments. No staff committee understands the detailed fiscal relationships of hospital management and all the salaried physicians who are members of the staff. The same may be said of the roentgenologists, who with anesthesiologists divide the bill for roentgenographic services collected for them by the hospital.

I shall not discuss how the present customs came about, nor the unpleasant consequences which until decently adjusted will continue to retard Blue Cross and Blue Shield expansion. There is hope that these differences may be settled, for the Massachusetts agreement gives a large measure of satisfaction. Blue Cross organizations have indicated that medical services now covered by their contracts will be transferred to Blue Shield when medical care contracts are widely sold, so that such transfer will not deprive large numbers of their clients of benefits to which they have become accustomed. The medical profession should always have clear control of all medical aspects of these plans which will be possible after this transfer. Anesthesiologists should all work to hasten that adjustment and make sure that it is enduring.

Some years ago Dr. Frank Lahey, in his address as president of the New England Surgical Society, warned that physicians must pay more attention to the management of hospitals or they will find themselves managed by hospitals. What I have told you of my own hospital experience can be repeated with variations by staff members of the community hospitals all over the country. It is not too late, however, to assert by deeds as well as words that a hospital without a staff is but a hotel. I agree heartily with Dr. Lowell Goin, who said, "It is the prerogative of the medical profession to decide on hospital policies when those policies concern the field of medical care;" and ". . . the trustees of hospitals included in reputable nonprofit group hospitalization insurance plans should be told what they must and must not do when the subject under discussion is the dispensing of medical services."

### COMMENT

Enunciation of principles, important as that is, is not enough. Anesthesiologists must develop the mechanisms to make those principles effective, and I suggest the prudential committee of the hospital staff as being a useful mechanism for this purpose. This committee should be trusted by management and staff alike. Its sole duty should be responsibility for the interests of the hospital, the staff and the employed physicians in the adjustment of their fiscal relationships and in wisely developing them to meet the needs of the community in the changing and complicated world in which we live. If every hospital could have such a prudential committee, endowed with foresight, temperate judgment and wisdom that conduces to moral virtue, we should move forward with confidence, knowing that we can adjust our present difficulties and meet successfully the calls of the future.

# FUNCTIONS OF THE AMERICAN BOARD OF ANESTHESIOLOGY

## Past, Present, and Future

PAUL M. WOOD, M.D.
New York

Anesthesiology—the study and practice of the art and science of anesthesia in all its forms and all that pertains thereto—began in 1846 as the clinical administration of one agent by one method for one purpose, the relief of pain. As a technical procedure it was relegated to anyone available at the time and place of administration. This drew the condemnation of John Warren,[1] President of the American Medical Association, in his address at Cincinnati in 1850. He said then that the administration of the anesthetic should be in the hands of a properly qualified assistant.

Anesthesia was accepted promptly by physicians the world over, but, in the United States, recognition as a specialty came only after ninety years. Early physician anesthetists were listed as surgeons, special interest: anesthesia. The Long Island Society of Anesthetists, founded in 1905, was composed of graduate physicians, licensed in New York, and most of them were members of the American Medical Association. Many of them were not surgeons, and, the age of specialism in medicine having dawned, they became directory conscious and desired official recognition of the equality of their specialty in education, ethics and practice.

Recognition of special qualifications in most organized societies is by means of committees or examinations. During the 1931 Congress of Anesthetists, held in New York, a committee was established to seek a proper means to designate a specialist in anesthesia. After two years of failure of twelve well qualified

Read before the Section on Anesthesiology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

[1] Warren, J. C.: On the Use of Anaesthetics, Tr. A. M. A. **3**: 385-387, 1850.

anesthetists to arrive at a solution, the New York Society of Anesthetists established in 1933 a Committee on Fellowship to attempt certification of anesthetists truly qualified as specialists. This group worked, by permission, copying the constitution and plans of the American Board of Urology. This work led to the formation on June 2, 1937, of the American Board of Anesthesiology, an affiliate of the American Board of Surgery. In 1941, it was recognized as a separate major specialty board. Experience gained by the Committee on Fellowship was of value in establishing regulations and examinations for the board.

The composition of a board is of utmost importance. Geography, finance, physical status, personality, educational background and type of practice must be weighed. All clinicians, all research workers or all professors would make a one-sided inadequate board. Time away from or in addition to regular work, to the extent of four to six weeks per year, is a consideration. Six year terms appear satisfactory. It takes an average of three years for new members to adjust to the routine, learn the regulations of the board and become useful members. To render sound judgments, fair decisions and accurate impartial investigations of irregular or unusual situations requires full attendance and open-minded and reasonable attitudes. These attributes have characterized the specialty boards in general and the Board of Anesthesiology in particular.

Several national organizations select three representatives (one of whom is elected a "member" of the Board), who present personal information of local problems from various parts of the country at the board meetings. Effort is made to avoid more than one representative from a city, but this is not always possible. The first board was composed of three representatives each from the Section on Surgery of the American Medical Association (there was no Section on Anesthesiology in 1937), the American Society of Regional Anesthetists and the New York Society of Anesthetists (which was originally called successively the Long Island, New York, then American Society of Anesthetists, now known as the American Society of Anesthesiologists, Inc.). The present board has ten members, four from the Section on Anesthesiology of the American Medical Association, four from the American Society of Anesthesiologists, one from the New England Society of Anesthesiology and one from the Section on Anesthesia of the Southern Medical Association. They came from Los Angeles; San Antonio; Rochester, Minn.; Hartford, Conn.; Cleveland; Providence, R. I.; Philadelphia; Tulsa, Okla.; Madison, Wis.; New York; Boston, and Reading, Pa.

The basic requirements of all specialty boards are similar or identical. Briefly they are: (1) graduation from a grade A medical school in the United States or Canada, (2) minimum of one year of internship in an approved hospital of the United States or Canada, (3) special training in the specialty, (4) membership in the American Medical Association, (5) time (five years) in the specialty and (6) examination in various forms.

The anesthesia board had no founders' group, all candidates having to meet identical standards. Standards were raised from a suggested period of supervised teaching, through a required one year, eighteen months and at present two years of required residency training. Preceptorship, though not advocated, may be substituted for approved residency time. This form of instruction varies with time and material facilities. Unlike approved residencies, which are relatively permanent, this form of training is limited to one student and one preceptor, mutually acceptable, and in each instance approved in writing by the board on recommendation of the Committee on Residency.

During the war, credit for service in anesthesia was given to a maximum of one year as residency training. This was an error, as too many could not satisfy the examination requirements without the supervised training. It is evident that quantitative clinical experience does not substitute for the didactic instruction, the conferences, seminars, literature sessions and laboratory research that comprise the special training now required and essential to a specialist certified in anesthesiology. Because of the war, other restrictions, as "grade A" and "United States or Canada," were occasionally set aside. This was only after due consideration and investigation, but it proved to be one of the pitfalls of expediency in emergency.

Here is a good place to correct some misstatements. Abe Martin intimated that often "it ain't what you don't know, but what you know that ain't so, that makes so much trouble." No specialty board is a union, and it does not issue degrees or licenses for any special practice. It merely sets standards for those who voluntarily seek its designation as "specialist." The boards do not approve or withdraw approval of residencies; this is the function of the Council on Medical Education and Hospitals of the American Medical Association, which makes the inspections and final decisions. It does confer with the specific board concerning specialty items, and the College of Surgeons is also invited to submit recommendations. The American Board of Anesthesiology has never required that heads of approved residencies must be specialists certified by the board. Some certified specialists have no special ability or desire to teach. This board knows that there are hundreds of physicians who are factually qualified to practice anesthesiology who would not or could not seek certification by this board.

If there were no human factors and no deviation possible from the printed regulations, then a machine could be set up to receive the credentials and fee, exhibit the examinations, evaluate the answers and issue a signed sealed certificate of qualification. Fortunately, rules made in good faith may for adequate reason be variously interpreted by the use of common sense, vision and integrity on the part of the members comprising the board.

This board is aware that its 100 per cent requirement of limitation is not always followed. It is not a sensible regulation from the point of view of education. It was adopted through expediency. Certificates have been withdrawn for failure to observe it. No candidate is put through an F.B.I. process, but the board does have an extensive and very efficient system of checkup on credentials. To date no person has been permitted to take the examinations if any member of the board knows that he does not comply with the 100 per cent limitation clause. No amount of rumor will institute revocation proceedings, but one single written complaint necessitates immediate and thorough investigation.

Examinations are abominations to all concerned. They have been used in some form in all known human endeavor to ascertain true fitness for special designations indicating proved qualities, and this board has found no substitute. It has, therefore, set up a system of three types of examination—written, oral and practical. One application covers all, and advancement is automatic on successful completion of a preceding part.

For the fee (currently $100), the candidate has two calendar years to pass each part; that is, he may have three chances at each examination, as today and one year and two years later. If the candidate should fail three times, he is required to file a new application and fee and begin again under the rules then in effect.

The written examinations were of the essay type until 1948, when a change was made to the multiple choice, International Business Machines type of examination. They are designed to cover basic science as applicable to anesthesia. The subjects or categories are anatomy, physiology, pharmacology, pathology, and chemistry and physics. The new type examination speeds the reports by nearly five months. Former reports were made by the three examiners to the secretary's office on candidates known to them only by number; the average was ascertained in the secretary's office, and no examiner knew the grades given by the other examiners. Where there was a variation of 20 points, books were sent to additional examiners. This system prevented favoritism, schools or indigestion from prejudicing a final mark. Candidates were notified only of "pass," "fail" or "condition," with no grade given. However, it was strictly observed that 75 per cent was required to pass. All questions of the essay type used in examinations were published at some time in *Anesthesiology*. The new type questions will not be published. Written examination may be taken after completion of two years of supervised training. Written examination is held the third Friday of each January, at ten different centers.

Oral examination is given only after completion of all the remaining requirements, as American Medical Association membership (through the County Society) and five calendar years of practice (including the special training period). The candidate meets all board members at the briefing session preceding the examination. He then appears before four regular and four associate examiners, two in each of four rooms. Discussion of each examination is held by the whole board and the associate examiners. Consideration is given to factual answers, attitude in answering and general impression made on all examiners. This method teaches the associates the plan of oral examination and prepares them as prospects for future board membership. Some have questioned the fairness of the examinations, but those willing to serve in them have been high in their praise after participation in the proceedings. A recent and valuable innovation is the "gripe session," conducted by a board member who has not participated in the examination. He receives voluntary verbal complaints or suggestions on any phase of the examinations, which makes the examinations following such sessions more valuable.

Those who fail are urged to confer with members of the Examinations Committee, who will go over their papers or oral reports. Nearly all have left these conferences convinced that they were fairly and properly treated. Errors can occur, and the board is prompt to make corrections if errors are proved. All candidates are assured that the board does not wish to set excessive standards, but, in the applicants' own interest, high standards must be maintained. Oral examinations are given during the third week of each October.

Practical examinations are given in all instances when no member of the board has observed the candidate work or the board does not know the local situation in relation to the problems of the anesthetist. It consists of a survey of clinical and theoretical work, of the equipment and local attitude of colleagues and associates in the candidate's own location or operating room. Report is made to the board, evaluated and, if satisfactory, is followed by certification.

Variations in the material covered and in the accepted answers caused an appeal for a fixed curriculum. Local working conditions do not permit a formal rigid pattern to be established in all centers. There is available through the American Society of Anesthesiologists and the American College of Anesthesiology a booklet, "Anesthesiology," giving in concise form the major requirements and reference texts. It will be sent on request to members of those groups or for a small charge (25 cents) to nonmembers. The outlines or patterns for three types of approved residencies are included in the booklet. They are adapted for a large hospital, a small hospital and a medical school-hospital combination department.

Residency approval forms should be requested from the Secretary of the Council on Medical Education and Hospitals of the American Medical Association, Chicago. Residency approval may be temporary or full. Full approval is in effect until the next inspection, at which time it may be renewed or withdrawn. Temporary approval is for an indefinite period, until the first inspection has been made. Termination of residency approval is on notice from the Council. Adequate opportunity is given for the hospital and for the residents to correct any unsatisfactory situation. When there are no satisfactory candidates from an approved residency, review by inspection should be expected. Cooperation with the Council has been prompt, full and satisfactory. Lists of 152 approved hospitals and 487 residency approvals are to be found in the May 1, 1948, issue of THE JOURNAL.[2] Some 35 additional hospitals have been recommended for approval since May 1.

Extra written and oral examinations may be given at intervals of six months with the regular examinations. Practical examinations are given at any time convenient for examiners and examinees. The certification of 424 physicians, establishment of 177 approved residencies, a Section on Anesthesiology in the American Medical Association, recognition in the House of Delegates, the statements of the College of Surgeons, the American Hospital Association and other national medical organizations that the practice of anesthesiology is the practice of medicine, all this with the growing acknowledgment of the increasing efficiency in this field of medicine by all physicians, and through them by more efficient, pleasant and safer service to the patients, is a certain strong indication of a favorable future for the work as instituted, carried on and projected for the years to come by the American Board of Anesthesiology.

131 Riverside Drive (24).

## ABSTRACT OF DISCUSSION

DR. PHILIP D. WOODBRIDGE, Reading, Pa.: The tendency of hospitals to require that every chief must be a certified specialist has put the boards almost in the position of being hiring halls for hospital staffs. This is an improper and unwelcome function for them. The boards would do well to educate hospital management to alter this stand. In the practical examinations only two candidates have failed thus far. These examinations should test the candidate's mastery of the art of anesthesia. Instead, they have become mainly an inspection of his working conditions. The nature or the name of the examinations should be changed, or they should be dropped. In several cases equivalent rather than identical standards have been used, in that written examinations were omitted and oral examinations became a formality. It is felt that long successful experience is evidence of intangible knowledge and skill, fully as important as the factual knowledge that can be tested in an examination. The recently adopted multiple choice type of written examination appears to test the candidate's detailed factual knowledge rather than his intelligence. Both should be tested if the value of certification is to be maintained. Membership in the American Medical Association is a requirement for certification. This smacks of trade unionism. A candidate should not be forced to join any organization in order to be declared a competent specialist. Concerning the 100 per cent limitations: The certified specialist may make a physical examination of a patient, provided that the patient is scheduled for operation, but if instead the same examination were to be paid for by an insurance company, he would be subject to revocation of certification. This seems somewhat parallel to the arrogant jurisdictional rulings of labor unions. It would be advantageous for the anesthesiologist to put in some time on cardiology, bronchioesophagology or neurology, but he is prevented from doing so by this restrictive requirement. Dr. Kirklin in 1941 wrote: "The requiring of one hundred per cent is excessive and unfair. . . . If the major portion of [a candidate's] practice is in his special field, he should be deemed eligible." One result of this requirement has been that a second certifying board, the American College of Anesthesiologists, has been set up, with a 50 per cent requirement. It is unfortunate that there should be two certifying boards in one specialty. It would seem better for the two to merge their functions into one board.

# REHABILITATION AND GENERAL PRACTICE

HOWARD A. RUSK, M.D.
New York

The practice of rehabilitation for the general practitioner, or for any physician, begins with the belief in the basic philosophy that the doctor's responsibility does not end when the acute illness is ended or operation is completed; it ends only when the patient is retrained to live and work with what is left. This basic concept of the doctor's responsibility can be achieved only if rehabilitation is considered an integral part of medical service. Any program of rehabilitation is only as sound as the basic medical service of which it is a part. The diagnosis and prognosis must be accurate, for it is on them that the feasibility of retraining is determined.

In addition to the general diagnostic studies, the medical evaluation of orthopedically handicapped persons must include muscle tests, tests of joint range of motion and tests for the inherent needs in daily living. In the Rehabilitation Service at Bellevue Hospital, a check list of ninety-six items is used to determine these factors.[1] They include: first, bed activities, such as moving from place to place in bed, and the ability to sit erect; second, toilet activities; third, eating and drinking; fourth, the ability to dress and undress, such as tying shoe laces, manipulating buttons, zippers and other fasteners, and applying and removing braces; fifth, hand activities, for example, winding a watch, striking a match and using various door knobs and latches; sixth, wheel chair activities, getting from the bed to the wheel chair, the wheel chair to bed and in and out of the bathtub, and, finally, elevation activities, which include the needed abilities for walking, climbing and traveling.

At first glance, such a test list sounds formidable and time consuming, but in reality the information may be easily obtained by a therapist, nurse, a well trained volunteer or a member of the patient's family. From the special check sheets used for charting the activity accomplishments, information is readily available both on the status of the patient at the time of admittance and his progress while undergoing rehabilitation.

The use of such a check list is particularly helpful if personnel are not available to do definitive muscle testing and accurate range of motion determination, for the daily activities test can be completed in the hospital, the physician's office or the patient's home. The subsequent training program is designed to teach the patient the various skills and activities which he cannot perform.

In Bellevue Hospital, after the basic medical work-up and the range of motion, muscle and needs of daily living tests, the physician, in conference with the therapists and other staff members, prescribes for the patient a full day's program, running from 9 a. m. to 4 p. m. These prescribed activities include training in the ambulation and elevation rooms and the remedial gymnasium, occupational therapy, physical therapy, speech therapy or any other activity which may be helpful in meeting the specific needs of the patient.

In a comprehensive rehabilitation program, vocational guidance specialists should also be available for guidance and testing, in order that the patient may be started on a prevocational exploratory and work-testing program as soon as it is medically feasible. However, good basic rehabilitation can be carried out with the personnel available in the ordinary general hospital, if such a program is properly organized, supervised and prescribed by the physician.

The rehabilitation of hemiplegic persons is a typical example. There are a number of simple progressive procedures in the rehabilitation of hemiplegic patients, one of the commonest disabilities seen in general practice. In the early stages of treatment, the following procedures should be instituted to prevent deformities:

1. Footboard or posterior leg splint to prevent foot drop
2. Sand bags to prevent outward rotation of the affected leg
3. A pillow in the axilla to prevent adduction of the shoulder
4. Quadriceps setting to maintain muscle strength

All of these procedures are relatively simple and require no special equipment. Their use, however, will prevent crippling anatomic deformities and hasten the rehabilitation of the patient.

The next procedure indicated is the institution of pulley therapy.[2] This can be done very simply with a small pulley attached to a gooseneck pipe over the head of the bed, using the ordinary clothes line rope with a 1 inch (2.5 cm.) webbing for the hand loop. With the stretching and passive exercise provided by pulley therapy, the range of motion can be increased and adhesions prevented.

Pulley therapy has the advantage over the usual stretching exercises that are done passively, for the patient knowing his own pain threshold will proceed to fully tolerated motion much more quickly. Pulley therapy can also be used to aid in the reestablishment of reciprocal motion patterns.

The patient, at this stage, should be encouraged to sit erect in order to reestablish balance. Speech therapy,

---

Professor and Chairman of the Department of Rehabilitation and Physical Medicine, New York University College of Medicine.

Read in the Session on Physical Medicine of the Section on Miscellaneous Topics at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

[1] A Test for the Activities Inherent in Daily Living, New York, Bellevue Hospital.

[2] Deaver, G. G., and Peterson, K.: Pulley Exercises to Increase Joint Movement, Arch. Phys. Med. 27: 17 (Jan.) 1946.

if indicated, should be instituted at this time. In the absence of a trained speech therapist, the speech reeducation can be started under medical supervision by any teacher who has had some experience in this field. In aphasic conditions, it is well for the physician to point out to the patient and family the nature of the condition in order that the inability to use the tools of language may not be interpreted as loss or diminishing of the ability to think and reason.

The next progressive stage in retraining hemiplegic persons is ambulation, which should be started by:

1. The practice of balance in the standing position progressing to parallel bars
2. The teaching of a heel and toe gait to minimize clonus and to reestablish normal walking habits and reciprocal motion
3. Use of a short leg brace, which will be needed in approximately half of all cases to correct foot drop

All of the equipment for training in ambulation is simple and readily obtained by the general practitioner. If parallel bars are not available, two kitchen chairs may be substituted.

In the advanced stages of retraining, ambulation is continued with:

1. Instruction in crutch walking, starting usually with the alternate four point gait
2. Teaching elevation, stressing climbing steps, curbs, stairs and ramps

Concurrently with training in ambulation, attention should be given to retraining in the activities of self care and daily living.

Obviously the physician himself cannot undertake the actual administration of the retraining, but the therapist, nurse, volunteer or even a member of the family can conduct the activities under his supervision. With such a program, many of the complications usually following apoplexy can be avoided and a great deal of time and ability salvaged.

A similar program of activity may also be started early with many arthritic patients. Passive and mild active motion, even when evidence of the acute disease has not completely subsided, can be instituted with caution, gradually increasing to a full program of activity as indicated by the subjective and objective symptoms. The rapidity with which the program may be advanced should be determined by fatigue, pain, swelling, febrile reaction and analgesic requirements. The sedimentation rate may also be helpful. However, in a number of cases of rheumatoid arthritis, it has been observed that patients, bedridden for a long time and from whom all activity has been withheld because of an elevated sedimentation rate, improved functionally and clinically, without exacerbation, with a carefully graded program of training and activity. In a number of instances, the sedimentation rate began slowly to fall after activity was started.

Presenting some of the most difficult training problems in rehabilitation are the quadraplegic and paraplegic patients. Although the rehabilitation of these patients is a mission requiring the teamwork of the orthopedist, the neurosurgeon, the urologist, the neurologist and in many instances the plastic surgeon, it is a rehabilitation problem in which the general practitioner plays an important role. His services are invaluable in maintaining the morale, nutrition and general health of the patient, and on his shoulders frequently falls the task of correlating the work of the specialists and interpreting it to the patient. In many instances, he must also make the decision as to whether rehabilitation should be attempted. This decision is one that should be approached with hope, courage and understanding, rather than the defeatist attitude that so frequently exists. Such an approach has been achieved in the Veterans Administration publication, "What's My Score."[3] The following paragraphs quoted from this publication are honest and factual but also give insight and hope to the patient:

> When the *spinal cord is completely severed,* it will *not grow* together again, and, up to now, no technique has been developed by medical science that will accomplish this and make it heal and function again. Some spinal-cord injuries are not complete and, in time, there may be some return to function.
>
> There are many diseases for which there are no cures, but medical science is finding out new things all the time. Twenty years ago, nothing could be done for diabetes and other similar diseases; now they are easily managed. A great deal of research is being done on nerve and spinal cord injuries, and some day we may get the answer. But at the present time, when the spinal cord is severed, there is no answer except YOU—you and your desire to live an independent life.
>
> Many men have done just this. This book contains their experience and the techniques they have developed. You can do the same thing if you get in there and pitch. . . .

Of the approximately 2,600 paraplegic veterans to whom that message was addressed, more than half have been taught to walk with the aid of crutches and braces and have left Veterans Administration hospitals ready for jobs or further vocational training. The case loads in the Veterans Administration's six paraplegia centers, however, have not decreased by a single case, as the rehabilitated patients have been replaced by patients with conditions resulting from peace time accidents.

As with the paraplegic patients, the general practitioner is forced to call on the services of medical specialists when dealing with patients undergoing amputation. However, he must assume the responsibility for preparing his patient physically and psychologically for the amputation and see that the patient has the proper prosthetic device adequately fitted and is trained in its use.

One phase of the management of the amputee to which the general practitioner should give particular attention is the immediate postoperative period, while the stump is being shrunk in preparation for a prosthetic device. During this period of six to eight weeks, the patient should be given graduated conditioning exercises in preparation for both crutch walking and the later use of the artificial limb, and measures should be taken to prevent anatomic deformities.

For example, it is not an uncommon practice in many hospitals following an above knee amputation to elevate the stump on a pillow. However, if such elevation is maintained for as long as two weeks, a flexion deformity will occur which will take from six to eight weeks of arduous painful work before sufficient hyperextension can be regained for satisfactory walking.

In advising his patient on the selection of a prosthetic device, the general practitioner must be aware of the fact that not all limbs are suitable for all amputees. In fact, he must realize that not all amputees can wear artificial limbs profitably. It has been noted on the rehabilitation service at the New York University College of Medicine that an above knee amputee in the older age group cannot, as a rule, profitably be trained to use a prosthesis if he is unable to perform a swing through gait on crutches.

---

[3] What's My Score, Publication 10-10, Veterans Administration, Washington, Government Printing Office, 1946.

The physician must point out objectively to the patient those skills which the patient can expect to achieve with proper training and those skills which the patient has little chance of ever regaining. Extreme caution must be taken in the latter, however, as it is unwise to tell a patient what "he cannot do," for this cannot be determined in most cases until the patient has had adequate training. Training is absolutely essential if the amputee is to be successfully rehabilitated.

One of the most pressing medical problems today is that of chronic disease, and in this field the general practitioner bears the brunt of the load. In 1940, the 26.5 per cent of the nation's population over 45 required over half of the nation's medical service. By 1980, it is expected that the number of persons over 45 will constitute nearly half of the population. We are living in the era of an aging population. A thousand years ago the average length of life was 25 years; at the turn of the century it was 49; today it is 66. In 1900, 1 person in 25 was 65 years of age or older; it is estimated that in 1980, the ratio will be 1 in 10. The chances are now 2 out of 3 that a young man starting his working life at the age of 18 will live to the retirement age of 65. A 45 year old man today has 70 chances in 100 of reaching the age of 65, and the chances of a 55 year old man are 87 in 100. The needs of this great group can be met only with a dynamic therapeutic program.

Age plus physical disability will prevent many persons from returning to competitive employment. Vocational placement, however, is not the only valid goal of rehabilitation. The factors of self care and the ability to do productive work while still living in a hospital, home or other adult institution are also valid objectives. They are valid medically and socially, for their effects on the well-being of the person and economically, in that the personnel and operating costs of the institution or the patient's home are thereby reduced. Using the known technics of selective placement, these persons should be allowed to work within the limits of their capacities. Work, properly prescribed, is one of the most valuable therapeutic tools in the treatment of geriatric patients and those suffering from chronic disease. The problems of chronic disease and the aging population can be met only by the creation and utilization of abilities, rather than the building of facilities.

In rehabilitation, as in definitive medical care, the general practitioner is an essential and integral member of the therapeutic team. Today, as new and mounting demands are made on him to restore his patients to maximum economic and social effectiveness, he must turn to the expanding field of rehabilitation and physical medicine for increased technical skills and assistance. However, he can apply many of these simple technics directly in his office, home and hospital practice to help his physically disabled patients "learn to live and work with what they have left."

### ABSTRACT OF DISCUSSION

Dr. Sedgwick Mead, St. Louis: Have you used Dr. Delorme's resistance exercises in the retraining of persons with hemiplegia or central lesions?

Dr. Rusk: I have found them helpful.

Dr. Mead: I have had persons with poor gait and atrophy superimposed on lack of control; after treatment these persons are able to take one step after another instead of dragging one foot behind the other.

Dr. Rusk: I have found building up muscle tone very helpful.

Dr. Weiss: Do you have any information about the rehabilitation of paraplegic patients in civilian life of the older age group. Veterans were a selected group of young men with far better potentialities. Have you any information as to the rehabilitation of the older paraplegic patient?

Dr. Rusk: I have had patients in their sixties, and I find a different motivation in the civilian than in the veteran, because the civilian is not protected by an adequate pension which will allow him to live at least without fear of want. I found in all age levels that in the civilian there is splendid motivation. I had 1 case recently at the new Institute of Rehabilitation of Physical Medicine in New York University. The patient was a 21 year old girl with a lesion of the sixth cervical segment, with no use of her triceps and inability to hold anything in her hands. She well exemplifies the fact that the vocational objective is not the total objective of rehabilitation. She could never be taught to walk, because she had no triceps function. However, I was able to make special gloves by turning the usual glove backward, cutting off the fingers and sewing the thumb across the palm. She could then place a knife, fork, spoon and toothbrush into the thumb of the glove and learned to feed herself and take care of her toilet needs. Another pair of gloves was devised with a peg arrangement in the thumb with which she was able to operate an electric typewriter. With the fitting of a proper wheel chair, she was able to get about the room unaided. These three simple things allowed her to go back to her home and accept a position as office manager in her brother's business, rather than spend the rest of her life as a home-bound invalid. I have found tremendous motivation in all age groups of hemiplegic and paraplegic patients, and the results of training have been gratifying.

# EFFICACY OF THE SUPPOSITORY AND OF JELLY ALONE AS CONTRACEPTIVE AGENTS

N. J. EASTMAN, M.D.
Baltimore
and
ROBERT E. SEIBELS, M.D.
Columbia, S. C.

One of the greatest obstacles to the prescription of contraceptives by physicians has been the belief that the diaphragm with a spermicidal jelly or cream is the only reliable method which the patient herself can employ. With this in mind, the physician recalls also the time-consuming features of fitting a diaphragm and instructing the patient in its use and as often as not side-steps the whole issue by omitting any form of contraception from his armamentarium. This contraceptive method was developed to meet some of the disadvantages of the sheath, especially the frequent unwillingness of the man to use it. It had the further advantage of putting the control of contraception in the hands of the woman, which was logical, as she was more available for education and more aware of the necessity; since she is the greater sufferer from an unwanted pregnancy, it was supposed that she would be more willing to learn the method and to use it regularly.

Under the direction of specialists the diaphragm served a useful purpose and suited the needs of a certain group of patients. However, its inherent disadvantages have kept it to a large extent restricted to the practice of the few, for, in general, the physician's interest in teaching a patient a prophylactic measure is much more apt to be sustained when a simple explanation is sufficient than when extensive instruction in technic is

---

From the Department of Obstetrics, Johns Hopkins University and Hospital, Baltimore, and the Bob Seibels, Jr., M.D., Memorial Laboratory, Columbia, S. C.

required. Many physicians find that the fitting of diaphragms, teaching the patient how to insert and remove them and requiring the patients to return for another check on their ability to insert and remove them carry disagreeable implications and are altogether too time consuming to be practicable.

The confidence of a physician in the method is badly undermined, furthermore, when he finds the literature recording disagreement among specialists as to whether the diaphragm should be inserted dome up or dome down; whether or when a douche should be taken, and with what solution, and whether the size prescribed should be ascertained by means of fitting rings or by the diaphragm itself, to enumerate only a few problems. All proponents of the method agree that there are certain women unsuited to the technic: notably those seeking premarital advice, those with extensive relaxation of the vaginal floor and those unable to learn how to insert and remove the diaphragm. The method is totally unsuited to the obstetrician with a large practice, who lacks the time to give the necessary instruction. Obviously, it is wholly unsuited to the large clinic, whether in the city, or in the rural areas, where the number in the postpartum clinic precludes the allocation of twenty minutes or more to each patient for this particular service. It is certainly not adapted to the needs of a patient in any walk of life who seems mentally incapable of understanding the method.

Indeed, it seems to some observers that the fundamental concept of the diaphragm as an occlusive agent is fallacious, as one can hardly expect a fit between the rim of the instrument and the vaginal wall close enough to prevent the passage of sperm to the posterior part of the vagina, and its only occlusion is of the cervix itself, preventing direct insemination. Examination of many patients with extreme anteversion of the uterus has demonstrated that often the cervix is caught by the rim of the diaphragm and is pushed back into the posterior part of the vagina, completely uncovered. In such cases the contraceptive value derived from the method arises solely from the jelly or cream associated with its use. When we investigate the actual use of the method by careful questioning of the patients, we discover that the majority of them regard the diaphragm as the important feature of the method and the jelly or cream simply as a lubricant; when they have no jelly or cream on hand, they use any material convenient at hand for its lubricating qualities. These factors, among others, explain why pregnancies occur in spite of regular but improper use of the method.

An advantage claimed for the diaphragm-jelly technic was that it permitted the physician to control the supplying of patients with the material and, therefore, left it to his discretion as to whether or not it would be prescribed; moreover, it gave the patient the added advantage of a pelvic examination which she might otherwise not have, at which time any existing pathologic process could be brought to her attention. These purposes were quickly defeated, however, as diaphragms and jelly were made available to purchasers through drugstores without the intermediary of the physician in the transaction, either to fit or prescribe the material. This arose partly from the desire of the patient to avoid payment of the physician's fee and partly from the unwillingness of physicians to fit the diaphragms. The jelly sold in these combinations seldom has good spermicidal qualities, and pregnancies occurring in spite of this use have further contributed to the distrust of patients and physicians of the value of the method.

In response to popular demands for a simple contraceptive, reasonably free of objections, various materials have been marketed under the names of jellies, creams and suppositories, and these have advantages of simplicity of use, from the point of view of the method's being readily understood by the patient and requiring the minimum of privacy for their insertion. Manufacturers learned quickly what physicians are often slow to grasp, that any therapeutic measure, requiring the unremitting cooperation of the patient as an important factor in success, must be simple to use and free of objectionable qualities. Thus the patient has forced the physician to consider seriously the merits of these simpler methods for his own as well as the patient's best interest. Similarly, in the practice of a large clinic, if the method which is simple can be demonstrated to be reliable and free of objection, much of the difficulty in supplying patients with a contraceptive is eliminated.

The requirements for a contraceptive are, in certain phases, more stringent than those connected with any other material prescribed. When it is recalled that the patient subject to cardiovascular renal complications of pregnancy has apparently a high rate of fertility and that for the true cardiac and the tuberculous woman a single pregnancy may prove fatal, one becomes aware of the urgent necessity that a contraceptive should be as effective as it is humanly possible to make it. A single live sperm circumventing the barrier to its entrance into the cervix is all that is required to bring about a train of circumstances upsetting to all concerned. Thus the contraceptive, under the various conditions in the vaginal tract, must have a higher efficiency rate than is required of any antiseptic. Secondly, it must be so free of objectionable qualities that the patient does not mind using it, and, to make it completely successful, it should have some qualities from which the patient derives, or imagines she derives, benefit. Many women retain their faith in douches not only because they are simple to take but because the odor of the solution, or its qualities of giving a pleasing after effect in addition to the cleansing, appeals to their aesthetic sense. This, again, has been made use of by manufacturers, who have endeavored to incorporate some of the qualities mentioned into their products, with a resulting popular appeal. It remains, therefore, to examine these products in order to determine what preventive qualities they may possess.

One of the difficulties in evaluating measures requiring patient cooperation lies in ferreting out the truth in regard to irregularity of use. Even in so simple a matter as a patient's taking iron for anemia of pregnancy, obstetricians find a great similarity between private patients and those in the clinics and experience difficulty in keeping more than 80 per cent of women regularly on the medication. One should, therefore, be willing to accept in the population at large about 20 per cent failure of patients to cooperate in the use of a contraceptive.

### BALTIMORE STUDY

With these circumstances in mind we decided independently, several years ago, to study the efficacy of certain simpler methods of contraception which did not entail the use of the diaphragm. Since in Baltimore an investigation had just been completed on the safety and value of phenylmercuric acetate as a contraceptive,[1] suppositories containing 0.05 per cent of this chemical were employed solely in that investigation. All patients were of known fertility, since they had recently been delivered of infants; none were lactating, and all were menstruating regularly and living with their husbands. All women in the study returned for check-up and additional supplies every two to three months. The following instructions were given:

---

[1] Eastman, N. J., and Scott, A. B.: Phenylmercuric Acetate as a Contraceptive, Human Fertil. 9: 33-42 (June) 1944.

1. Keep suppositories in a cool place.
2. Remove the tinfoil covering before using.
3. Insert the suppository as far as possible into the vagina (birth canal), before each and every sexual relation.
4. The suppository melts in the vagina in —— minutes,[2] and you must wait at least this long before having sexual relations.
5. Do not wait more than thirty minutes after inserting the suppository.
   If you do wait more than thirty minutes, you must insert another suppository before sexual relations.
6. Lie flat in bed for at least two hours after sexual relations. Do not douche.
7. Wait at least six hours after relationship before douching and then douche with warm soapy water.

In order to make certain that the suppositories would be acceptable to husband and wife and in order to eliminate as much as possible half-hearted and irregular users, a trial period of six months was allowed before the patient was actually included in the investigation. In other words, in addition to the 333 women listed in table 1, more than 150 patients were given suppositories but had to be omitted from the study because (*a*) they did not return after the first or second visit and could not be traced, (*b*) they did not like suppositories and changed to some other method, (*c*) they exhausted their supply of suppositories or (*d*) they found themselves pregnant during the first month or two after using the suppositories. There were 14 known pregnancies in this group and possibly others of which we do not know. Because of the time relationships several of these 14 pregnancies may have existed at the time suppositories were first used. These failures may be added to those shown in table 1 and the results recalculated if desired, but it is quite impossible to state with even approximate accuracy just how many weeks or months, or how regularly, this group used the medication.

TABLE 1.—*Contraceptive Efficacy of Suppositories in 333 Patients (Nov. 1, 1943-March 1, 1948) in Baltimore Study* *

| Number of Patients | Months Suppositories Used | Patient Months | Method Failures | Patient Failures |
|---|---|---|---|---|
| 41 | 6 | 246 | 6 | 3 |
| 37 | 7 | 259 | 3 | 5 |
| 21 | 8 | 168 | 2 | 4 |
| 32 | 9 | 288 | 5 | 1 |
| 17 | 10 | 170 | 2 | 2 |
| 18 | 11 | 198 | 3 | 0 |
| 15 | 12 | 180 | 4 | 1 |
| 19 | 13 | 247 | 3 | 0 |
| 17 | 14 | 238 | 1 | 1 |
| 24 | 15 | 360 | 3 | 0 |
| 16 | 16 | 256 | 1 | 0 |
| 15 | 17 | 255 | 2 | 0 |
| 10 | 18 | 180 | 0 | 0 |
| 5 | 19 | 95 | 1 | 0 |
| 4 | 20 | 80 | 0 | 1 |
| 11 | 21 | 231 | 2 | 0 |
| 3 | 22 | 66 | 0 | 0 |
| 8 | 23 | 184 | 0 | 0 |
| 9 | 24 | 216 | 1 | 0 |
| 3 | 25 | 75 | 0 | 0 |
| 1 | 26 | 26 | 0 | 0 |
| 4 | 27 | 108 | 0 | 0 |
| 3 | 28 | 84 | 0 | 0 |
| 333 | | 4,210 | 39 | 18 |

* When calculated according to 100 woman-years of exposure to conception, by means of the usual formula ($R = 1200 \times \frac{\text{Conceptions}}{\text{Months of Exposure}}$), the pregnancy rates were as follows:

$$R \text{ (method failure)} = 1200 \times \frac{39}{4{,}210} = 11.1$$

$$R \text{ (total failures)} = 1200 \times \frac{57}{4{,}210} = 16.2$$

TABLE 2.—*Efficacy of Diaphragm and Jelly as Reported in the Literature*

The patients who returned and stated that they did not like the suppositories gave the following reasons: (1) Neither husband nor wife had confidence in suppositories, since they had always heard that the diaphragm was the safest method; this was the commonest explanation (35 cases); (2) irritation on the part of the husband (5 cases); (3) irritation on the part of the wife (3 cases), and (4) too "messy" (7 cases). In looking back over the histories of the 333 women who used suppositories six months or more, it was found that 6, or 2 per cent, had complained of some irritation on the part of either the husband or the wife when the suppositories were first employed, but they observed that this had not recurred after the first or second use.

The results of the Baltimore study are shown in table 1. "Patient failures" are those in which the woman acknowledged that she had failed to use the suppository on one or more occasions. "Method failures" are those in which inquiry failed to obtain any acknowledgment of coitus without preceding insertion of a suppository. Because of personnel shortage during and after the war, it was not possible to visit these patients in their homes as much as would have been desirable, and this apparent lack of interest and encouragement on our part may be the cause for the higher rate of failure in Baltimore than in Columbia. This important aspect of the problem will be touched on again in connection with the Columbia study. However, although the gross figure of 16.2 pregnancies per hundred woman-years of exposure[3] may appear high when compared with the South

---

[2] Melting time is determined in each patient and written here. It varies between 4 and 10 minutes in different patients.

[3] The term "pregnancies per 100 woman-years of exposure" has become the standard method of expressing conception rates with or without birth control procedure. In calculating the period over which a given woman has been exposed to conception, intervals during which she is pregnant are omitted, because another conception is obviously impossible at that time and hence she *cannot* be considered as exposed to it. For example: If a woman has had six full term pregnancies in ten years of married life, the period over which she was exposed to pregnancy would be one hundred and twenty months (period she was married) minus sixty months (period she was pregnant) or sixty months, or five years. If 20 women with an identical experience were observed, there would be 100 woman-years of exposure during which time one hundred and twenty conceptions occurred, that is, the pregnancy rate would be one hundred and twenty for the hypothetic group.

Carolina record, it compares favorably with the reported results with the diaphragm and jelly, as tabulated by Beebe[4] and reproduced in table 2. On the basis that the preclinic pregnancy rate of our patients was similar to that commonly reported (table 3), the reduction in fertility in the Johns Hopkins study would be of the order of 85 to 90 per cent.

### SOUTH CAROLINA STUDY

The prescription of contraceptives on a rather large scale has been under the supervision of one of us (R. E. S.) in the clinics for postnatal patients and those undergoing antisyphilitic treatment under the South Carolina State Board of Health. The clientele of these clinics is largely rural Negro, averaging in education about fifth grade in school. Obviously, fitting of diaphragms was beyond the scope of the limited personnel with the large population they had to serve, and thus was reproduced on a large scale the problems of city clinics, with a possible difference of mental level.

During the years 1941-1947 various methods were used, with the results shown in table 3. Here it may be seen that the South Carolina study represents a composite of twelve separate investigations, in which various contraceptive agents were employed. The number of patients followed (line B) ranged from 41 in one investigation to 197 in another, with a grand total of 1,573 women followed. The women-months of exposure while the contraceptives were being used (line F) varied between 571 and 3,491, with a grand total of 21,088. Seventy-nine conceptions occurred (summation of line G). By reading line H across it will be seen that the conceptions per hundred years of exposure were surprisingly low, the over-all average for regular users of the methods being 4.5.

The figures, it should be noted, are from those claiming to be regular users only, as this group seems the logical one for evaluation of the pregnancy preventive factors concerned. A study of reports from irregular users might throw light on various phases, such as acceptability of the material, the extent to which a patient was interested in contraception and the ability of a group to use material regularly. None of these are pertinent to our inquiry, which was primarily directed at the percentage of reduction of fertility which could be brought about by regular use of the material distributed.

Some observers have tended to discount the South Carolina figures because of the fact that we do not include irregular users. This, it seems to us, is no more fair than evaluation of the effect of iron in simple hypochromic anemia on the basis of the mass distribution of iron and then recording the change of hemoglobin regardless of whether the patient used it occasionally, rarely or not at all. Because of the type of patient to whom material was distributed, there was necessarily in the group a certain number not convinced of the need for pregnancy prevention, because of superstition or other reasons, and some mentally incapable of carrying out the simplest directions except under supervision. Many of them were careless with the material and allowed it to be destroyed or, where mechanical appliances, such as applicators, were essential, lost them, broke them or allowed them to be filled up with dried material so that they were unfit for use.

It is true that we do not know to what extent regular and unremitting use was the practice of those who did not become pregnant; nor do we know how to arrive at the answer to this question. It is possible that many of the women were irregular in their practice, and their being relatively or completely infertile may have served to give a higher figure than would be derived with all the facts available. However, it is believed that in a study of this sort, covering so many patients over so long a time, the factor of irregular use not followed by pregnancy is a fairly constant one, running through the series.

Effectiveness measured by reduction in fertility is rather high in this series. Certain factors entered into the success achieved which probably were not present in other series. In the first place, we learned by experience not to count a patient as an active user until she had at least two regular periods after being supplied.

[4] Beebe, G. W.: Contraception and Fertility in the Southern Appalachians, Baltimore, Williams & Wilkins Company, 1942.

This eliminated patients who were pregnant at the time they were supplied, which, in an earlier series, was found to be around 8 per cent. We felt it unfair to the material to blame it for its lack of spermicidal qualities until we found that the patient was not pregnant when she began to use it. This rule also had the value of eliminating from our list women who were only mildly interested who often caused us to wonder, when they became pregnant shortly after they had been supplied, whether they had ever used the material. The one important reason for the success achieved in this series was that the patient was seen either at the clinic or at home not less than every six weeks and was checked as to supplies on hand, so that she would not be out of material and also to determine whether or not she was using it. These visits served to encourage the patient in the use of the material or to report its nonuse and played the same useful role that the frequent visits to the office during her prenatal care afford in encouraging the patient to carry out the obstetrician's directions. We rather deliberately put the study shown in column 8 in a clinic where it was impossible to have these frequent visits. The material was given out to the patients, and they were instructed to return for more when they needed supplies; no special effort was made to encourage them to use it, since, in that county, health department personnel was rather limited and none of the nurses could give time to it. When the results in this county are contrasted with those in column 7 with the same material, we see the recurring figure of approximately 20 per cent difference in effectiveness, which we attributed to lack of use or irregular use where the indifference of the patient was not overcome by the encouragement of the nurse visitor.

An interesting by-product of this study answers rather satisfactorily the question as to whether these materials tend to produce sterility. We found that there were certain regular intervals when we could expect pregnancy following irregular use. These occurred in the third, twelfth and eighteenth months. It is during the first three months that the irregular user first comes to light. Again, at the twelfth and eighteenth months many of the patients have felt secure that they would not become pregnant. They were unable because of their mentality to connect the lack of conception to regular use in a direct causal manner and often became irregular users. We found in these patients conception apparently took place within two months after irregular use became the rule; in a number of cases in which contraception was prescribed for the spacing of conception and another pregnancy was desired, there were no reported instances where there was failure to conceive. While this feature was not followed out in any extensive manner so that percentage results could be published, we certainly were impressed with the observation that sterility was not increased in this series by the use of the material.

It would be highly improper to draw any conclusions as to the relative effectiveness of the various methods listed in table 3 based on percentages, since careful analysis of the figures shows that these differences are more apparent than real. Often a contraceptive agent showed better results when subjected to a twelve month study than to one of twenty-six months, and it is possible that during the twelve months' study, some of these patients were relatively infertile and might not have become pregnant had they not used any contraceptive. However, it must be recalled again that effectiveness depends primarily on acceptability and, in general, the simpler the method the more acceptable and, therefore, the more effective. We believe, therefore, that a suppository containing the same material found in a cream or a jelly will prove more effective on a large scale because its use is simpler.

## SUMMARY AND CONCLUSIONS

Two separate studies are reported evaluating the efficacy of certain simple methods of contraception which do not entail the use of the diaphragm—one carried out in Baltimore and the other in Columbia, S. C., and vicinity.

In Baltimore 333 women, who used a suppository containing phenylmercuric acetate as the only contraceptive agent, were followed for intervals which ranged between six and twenty-eight months. The total period of exposure to pregnancy of these women while under observation was 4,210 woman-months. Fifty-seven conceptions took place, or 16.2 per hundred woman-years of exposure. In 18 of these 57 cases the woman acknowledged failure to use the suppositories on one or more occasions. Subtracting these, there were 39 conceptions which occurred despite the regular use of the suppositories, or 11.1 per hundred woman-years of exposure.

In the South Carolina study various types of simple contraceptives were used, including jelly alone, cream alone, suppositories, and sponge and foam powder. Fifteen hundred and seventy-three women were followed for intervals which ranged between twelve and thirty-seven months. The total period of exposure to pregnancy of those women while under observation was 21,088 patient-months. Seventy-nine pregnancies occurred despite the regular use of the contraceptive agent, giving an over-all average figure for the non-diaphragm methods of 4.5 conceptions per hundred woman-years of exposure.

As may be seen in table 2 the efficacy of the diaphragm and jelly in New York has been reported as low as 12 conceptions per hundred woman-years of exposure and in other cities of the United States from 15 to 18. On the other hand, in San Juan, Puerto Rico, the identical method has yielded a figure of 33. This shows clearly that the end results of any birth control program will depend more on personal factors (such as earnest desire to prevent conception and intelligence) than on the inherent efficacy of the procedure employed. The divergency of the figures reported in the present study doubtless reflects the same circumstance. Moreover, the sources of error in calculating results are many, and, all in all, statistics on the intrinsic value of any given method must be regarded as approximations only. Although the present study is vulnerable to all these criticisms, it at least raises the question as to whether the superior efficacy of the diaphragm over other procedures has not been greatly exaggerated. It may be that certain women, highly skilled in the insertion of the diaphragm, will receive better protection from that technic, but surely mass studies on the diaphragm have not shown greater efficacy than is reported in this paper by simpler procedures. Hence, the conclusion would seem inescapable that these latter methods—especially the suppository, the simplest of them all—deserve more widespread trial than they have heretofore received.

## HISTORICAL BACKGROUND

To decide who was guilty or who was right between two litigants, Birmanian tradition prescribed that two candles should be simultaneously lighted and given to the litigants. The first to go out was the one in the hands of the guilty or wrong party. A divinity was also supposed to protect the innocent person against the damage of a testing substance that he was made to swallow, or enable him to walk on red hot iron, or extract a ring from the bottom of a caldron full of boiling water or go through other such queer and extraordinary trials that people conceived in different ages and regions. They were the mediums of God's judgment: the ordeals, or *Dei iudicium.* Sometimes individual prowess was replaced by a duel, in which one of the two fighters was a gentleman or a champion who defended his lady or his master. Might is right: the strongest must win and deserves to win. Perhaps as a rebuttal, Voltaire said, many years later, that God was always on the side of the larger cannons. According to their respective idiosyncrasies the ordeals developed, in France, toward torture and in England toward the jury. In the former, truth was routed out by pain and, in the latter, guilt was ascertained by other citizens who might have cherished like passions or gone through conditions similar to those of the accused. These thoughts arise from the contemplation of the pubic health panorama. Doing so, one feels subjected to a test that would be unbearable if one were not sustained by an unshakable faith in the value of a sound public health policy.

## ROLE OF THE SANITARIAN

The sanitarian, on preparing his plans, proceeds much as the engineer: he looks for the data and analyzes, treats and presents them for his own use and for that of others, drawing from them the pertinent conclusions. He acquires this system, thanks to epidemiology which is essentially a methodology. As a physician he was not inclined to act so, for medical practice is, even today, an art, in which intuition is of more avail than method. In advanced countries, predictions are difficult, even granting that future events are mainly the results of the development and extension of those past and present. It must be so, since in the route of progress they open a path and mark a trail. On the contrary, we, the smaller and younger countries, navigate on a charted sea.

This land is propitious for the development of specialists. It has been said that specialization is a centrifugal force which is tearing culture asunder. But this does not matter now. What does matter is that it is enough for a medical officer in the United States to be well acquainted with the prevailing conditions of the population under his care to perform his tasks correctly. We, on the other hand, must divide duties among a handful of men and, consequently, have to know the most diverse facts and developments from the beginning to what was published in today's paper.

## ECOLOGIC DATA

It is true that North Americans are the product of many races which have blended in the crucible of this enormous country, and one can still perceive the existence of different groups. However, the phenomenon appears rather as the implantation of many grafts in the single Anglo-Saxon stem. A group of mature and peaceful people crossed the Atlantic and settled on this side. They brought with them many of their traditions and ways of living. That is why the War of Independence is called a revolution.

To Chile, on the contrary, came a conqueror, armed to the teeth and motivated by domination and plunder. Pedro de Valdivia brought with him a priest, because he was concerned about the future of his soul, but not a physician, because he came to kill and not to heal. The wounded soldiers were under the care of his lady friend, Inés de Suárez, who was the only woman of the expedition and by whom he never had children. With minor variations, the same story is repeated in Colombia, Perú, Mexico and in other regions. The first solid buildings of the new colonies were the fort and the church. The principal square of our settlements was called Plaza de Armas (Arms' Square). Surrounded by the church cathedral, the houses of the governor and of other prominent persons, it was devoted to soldiers' exercises and parades.

To counteract the vanity of those who say they are descendants of the Pilgrim Fathers of the Mayflower, an American humorist used to boast that his ancestors had been present among those who came to welcome them. The same must have been true of ours. In any case, in Latin America appeared new and different nationalities, which were the product of the mixing of two races which credibly had never been crossed before.

From the crossing of the Spaniards with the natives a new genetic line emerged, the most outstanding characteristic of which is its ability to adjust to new conditions of physical and social surroundings better than any of the parental strains. Together with the ecologic improvement, there is an increased virility from the reproductive standpoint. Large families—of 16, 20 or over—were common in the colonial period, but the death rate, already high, was raised by the new epidemic diseases introduced by the invader. Smallpox helped Cortés to conquer Mexico, and typhus was on the side of Pedro de Valdivia in Chile, to mention just two examples. Consequently, the population did not increase noticeably, but a new and solid stratum for the incipient nationality was formed. This is still intact in the rural areas and small towns, In larger cities new European blood has been added to dilute the native blood further. It has always been difficult for me (H. R.) to fill in the racial item in forms. I do not like to consider myself white, and I could hardly say that I am dark.

## GEOGRAPHIC ASPECTS

When I first arrived in the United States one of the most annoying experiences was that of being referred to professors of and courses on tropical medicine. In spite of the latitude of the northern part[1] of our country, we have no tropics, thanks to the cold Humboldt current, the one that prevents bathers from remaining too long in the water at our beaches.

The Humboldt current equalizes the temperature, so that there is only a small difference between the mean temperatures of the extreme north and of the extreme

Because of lack of space this article has been abbreviated in The Journal. The complete paper will be found in the authors' reprints, which the authors will be pleased to send on request.

[1] The tropic of Capricorn passes through Antofagasta, and one seventh of the territory is in the tropical zone.

south, and the Cordillera wards off the continental influence of winds from the Argentine pampa. Consequently it never rains in the north of Chile, and toward the center it rains only during winter. At the peak of agricultural activity, in the summer, the land has to be irrigated, which entails great effort and is not always feasible. In certain regions our climate, as benign as in New Zealand and the islands of the South Pacific, is as pleasant to live in as it is adverse for agriculture.

### POPULATION FACTORS

As we have no tropical crops and have been proverbially poor since colonial times, the Spaniards did not bring Negroes. Chile did not have the slave market that left its traces in other parts of Latin America. When a Negro is seen in the streets people usually turn around to look at him and surmise that he is a boxer or a jazz band player. Nor do we see many Orientals, although there are plenty on the southern coast of Perú. Probably because of this, some of us are entirely lacking in racial prejudices. They are so foreign to our preoccupations that no item for race is included in the census forms in Colombia, Venezuela and Chile.

* From Hill, J. A.: "Composition of the American Population by Race and Country of Origin, Ann. Am. Acad. Polit. & Soc. Sc. **188**: 177-184 (Nov.) 1936.

Our Indians were less civilized than their neighbors and of extraordinary courage. Most of them preferred being killed to surrendering, and we probably have less native blood than other nations, only that of the basic layer we already mentioned. This is true of the southern triangle of the continent: Uruguay, Argentine and Chile. In Perú the indigenous population constitutes approximately 50 per cent, and in Mexico a handful of Europeans maintain a precarious balance with the original inhabitants. The conflict looks sharper, considering that the Indians were actually worthy and cultured. No society, to our knowledge, has attained a clearer or more intellectual concept of the state than the Inca; it is hard to conceive a more daring engineering with simpler elements than that practiced by the Mexicans or Bolivians; and whoever values the pleasure of a beautiful combination of colors may well go to Guatemala. It is comprehensible for those countries to talk of Indoamerica, an idea hard to grasp for Uruguayans, Argentineans and Chileans.

When one goes back home from the States there is always an American who asks to be remembered to a Restrepo in Bogotá or to a Souza in Río de Janeiro. It is explainable, because one thinks of Latin America as the United States of the South, which it should be but is not. Our evolution has been conditioned by geography, which has raised tremendous difficulties for communications and has obliged us to remain apart and become differentiated from one another. Previous to the advent of the airplane, Caracas and Asunción were absolutely remote for us. In colonial times Spain compelled us to trade exclusively with her, forbidding intercolonial commerce. The bilateral treaties of the United States have not contributed to this end either.

Chile has grown gradually and should have, by 1950, some 6,000,000 inhabitants.[2] The population increase has been slow, because the increase has been due mainly to the vegetative growth or natural increase, that is, the balance between births and deaths. We have not received immigration waves of hundreds of thousands as in this country and, to a similar extent, in Argentine. Our largest inflow took place toward the middle of the nineteenth century, consisting of a handful of intellectuals who were fleeing from Europe after the failure of the liberal uprisings of 1830, 1840 and 1848. It determined the development of the southern part of Chile, which has been called, with obvious exaggeration, Naziland. A comparison of census results (table 1) of the United States and Chile will shed light on the rate of growth in general, as well as that corresponding to natural increase in both countries.

This number of censuses, an exception in America, may be surprising to some. By way of a historic curiosity, we may mention that Cuba and Puerto Rico each had one, in 1764 and 1765, respectively, but up to now the system has not taken root in our countries. As far as South America is concerned, Brazil, Venezuela, Colombia, Ecuador, Peru, Bolivia and Paraguay had, in 1940, data on only part of the territory and estimations on the rest. Only Uruguay, Argentine and Chile are in a position to carry out nominal and direct census. For other reasons, the two former have not taken one since 1908 and 1914, respectively. We understand that Argentine has completed one recently and 1950 has been set for the census of the Americas, the importance of which cannot be overestimated.

Since Pearl's time[3] we know that population growth, be it of men or banana flies, follows a certain pattern, known as the logistic curve.[4] It sounds absurd and incredible until the data are projected on a curve. The similarity in the history of population growths of different countries is really astounding. At the start, birth and death rates—from infant mortality as well as from all causes—are always high. Because of a surplus of births over deaths, the population increases gradually at first and gains speed as the difference becomes more pronounced. Later it diminishes to the extent of reaching a stabilization phase and even a decline.[5] Its shape is suggestive of a plane that takes off. First it runs along the field and then gains altitude and rises until it levels off.

---

[2] Chile had 5,820,695 inhabitants Jan. 1, 1948.

[3] Pearl, R., and Reed, L. J.: On the Rate of Growth of the Population of the United States Since 1790 and Its Mathematical Representation, Proc. Nat. Acad. Sc. **6**: 275-288 (June) 1920.

[4] The mathematical formula was first established by the Belgian mathematician Verlhust. The curve describes the phenomenon so well that some authors have spoken of a law of population growth (Pearl and Reed), which others question or do not accept (Wilson, E. B., and Puffer, R. R.: Least Squares and Laws of Population Growth, Proc. Am. Acad. Arts & Sc. **68**: 285-382 [Aug.] 1933). The logistic starts from a population that, at the beginning, grows little in absolute numbers (the lower asymptote), whose growth first increases rapidly and then recedes progressively, until around the inflection point the growth is stabilized. When the population has come to a standstill the maximum limit has been reached, that is to say, the greatest number that the region can maintain with the resources at its disposal and within predictable progress. Naturally, this limit is not absolute and can be removed or modified by the influence of important changes. This is what happened, for instance, in Puerto Rico, beginning with North American domination (Janer, J. L.: Population Growth in Puerto Rico and Its Relation to Time Changes and Vital Statistics, Human Biol. **17**: 267-313 [Dec.] 1945), and in Germany, with the industrialization that followed victory after the Franco-Prussian war (Pearl, R.: The Curve of Population Growth, Proc. Am. Philos. Soc. **63**: 15-17, 1924).

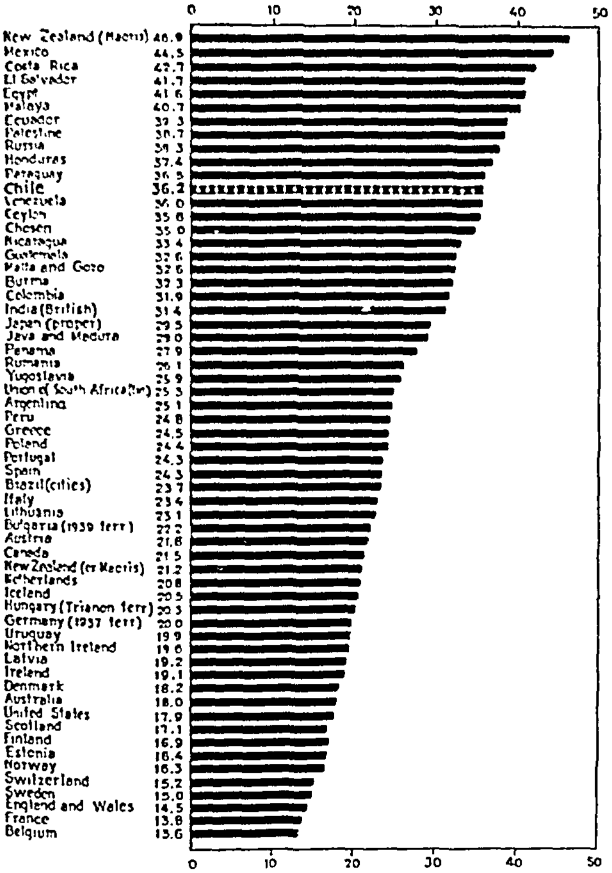

Fig. 2.—Crude birth rates (per 1,000 population) in sixty countries for 1940. (The data in this and other charts [figs. 3 and 4] were obtained from the Summary of International Vital Statistics for *1937-1944*, United State Public Health Service national office of vital statistics.)

A comparative graph of the growth tendency of the populations of France, United States and Chile would demonstrate that France is approaching stabilization and we are left far behind. But even if our present position is equivalent to that of the United States in 1875, it will not necessarily take us seventy years to reach her present situation, since nowadays everything moves at a greater speed and we know today much that the Americans then ignored. The same graph would reveal that we needed one hundred and fifty years to cover the logistic arc that the United States completed in 70. The realization that we are following the path of other nations, induces us to reassert that we are sailing on a charted sea.

In accordance with this conception, Chile is in the second phase of her demographic history. She has one of the highest birth rates (35 per thousand inhabitants (fig. 2) and her infant mortality (143 per every thousand live births) (fig. 3) and general mortality (17 per thousand) (fig. 4) are still very high. These rates have followed parallel tendencies in all countries whose history is recorded, with the exception of New Zealand. They naturally produce a young population with a small life expectancy. Actually, ours was, in 1940, 41.8 years,[6] a small figure compared with that of the United States, but similar to that of other Latin American countries.[7]

With the age distribution that occurs in Chile, infectious diseases, and particularly tuberculosis, should prevail and chronic and degenerative diseases should be less frequent. Infant mortality, together with tuberculosis mortality, constitute approximately 50 per cent of all deaths, a feature which should set the North in our sanitary compass. On the other hand, cancer is not such a problem, although chances of dying from it are the same in every age in both countries. Youth also shapes people's behavior and this fact probably explains why our political organizations are neither very stable nor very serene. Fortunately, Chile has a solid administrative setup, in such a way that rulers and politicians as individuals do not usually modify the main direction of the country. That is why we are certainly the best behaved country in Latin America.

It is said that when enterprises are in the hands of young persons many mistakes are made and when managed by older persons nothing is achieved. The former may still be our condition, and probably the United States has not yet reached the latter. In any event, a large proportion of persons who are intellectually and economically mature makes it possible

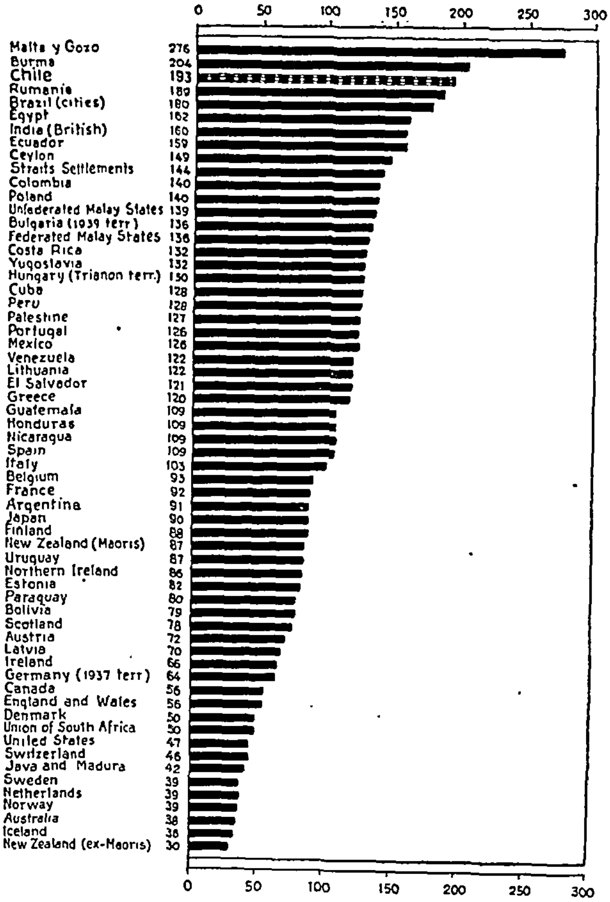

Fig. 3.—Infant mortality rates (based on the number of deaths reported of infants under 1 year of age per 1,000 live births) in sixty countries for 1940.

---

to have better trained workers and higher salaries, continuity in commercial and industrial concerns and, consequently, a higher standard of living.

As we are few and we die young, it would be advisable to prolong our productive period. In the United States compulsory retirement is necessary, since older persons who are still strong have to step aside, in order to leave their places vacant for younger folk. For us, conditions are the opposite. Notwithstanding, our social laws give great facilities for retirement and our national budget is unduly burdened with pensions for persons who should be working for the community.

It is a common fallacy to believe that national wealth depends on a growing population and that it is therefore necessary to be concerned with the magnitude of birth rates. According to Raymond Pearl, Dunn says that our planet is going through an epidemic of population growth. In fact, toward the middle of the sixteenth century it held some 445 million persons, and this figure has now reached two billions. This means that in the last three hundred years, one-thousandth part of the known existence of man, the world population has been increased about five fold. It continues to grow at a rate of 1 per cent annually, i. e., about 20 millions. The human species is passing through what zoologists term a breeding storm, which may be attributed to the progress of science that has conquered uninhabited regions, perfected crops, developed new sources of energy and performed other extraordinary feats.

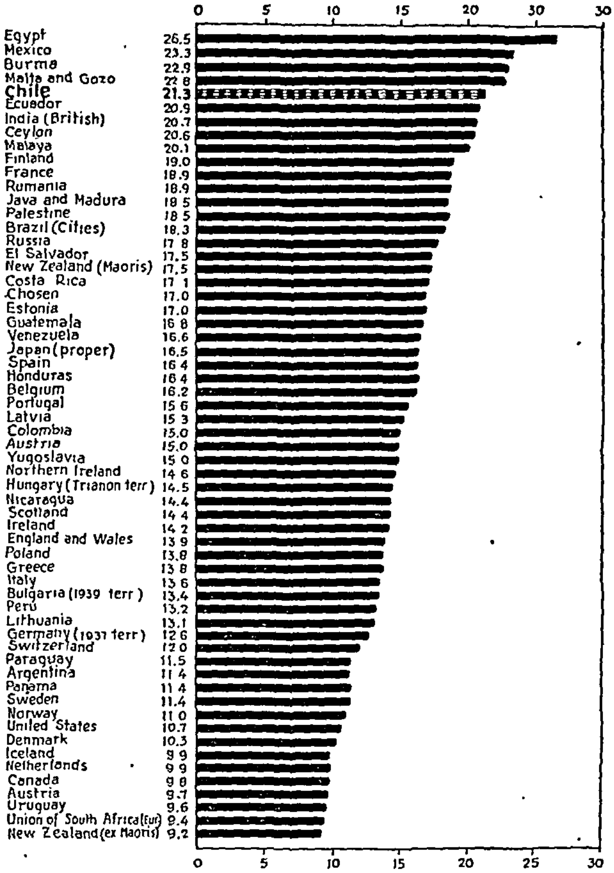

Fig. 4.—Crude death rates (based on the number of deaths reported per 1,000 population) in sixty countries' for 1940. (Unless otherwise specified, war losses are included.)

Comparing the active population of Chile with that of the United States, we see that here a larger proportion is employed in manufacturing and 18 per cent in agriculture, against 34 per cent in Chile. Chile should then be classified as an agricultural country although, as we have already stated, topographic and climatic conditions are rather unfavorable. The contradiction is explainable, because the mining companies are in the hands of foreigners who take away the raw material, returning only the costs of mining and not those of manufacturing and elaboration.

From a public health point of view, the nations of Latin America could be classified in three groups: (1) Those who have a relatively homogeneous population and many persons with a high standard of living, plus an abundance of resources, and no hinterland. In those countries tropical diseases do not exist or are of little consequence. Whoever goes to Montevideo, in the purple land of Hudson, will find a European city transplanted to our continent, and in many aspects Argentine has a higher standard of living than the United States. (2) The second group is the opposite of the first. (3) The third is similar to the first, but has a low standard of living complicating sanitary problems. Here we place Chile.

### ANALYSIS OF MORTALITY RATES

In reality, Chile has no sanitary problems due to its geography. They are all derived from human convergence and civilization or, shall we say, lack of civilization. There were some malarial spots in the valleys encased in the northern deserts. They were eliminated by an efficient sanitary campaign and now require only control. On Easter Island, in the middle of the Pacific, there is a handful of lepers forgotten by the gods. Toward the south there is hookworm in the coal mine shafts which extend under the sea and provide a humid and warm atmosphere propitious to the worms. The hookworm, it may be mentioned is the Ankilostoma duodenalis from Europe and not the Necatur Americanus of this continent, because these mines were developed by Scotsmen who brought the worm. It is rightly said that the visiting card records one's name and the intestinal parasites the place of one's origin. Recent investigations have brought to light endemic centers of Chagas disease, the extent of which has not yet been ascertained. In spite of the fact that the whole country is a coast line, there are cases of endemic goiter in some regions where the mountain ranges ward off the sea breezes, but not any of these factors or all of them put together really weigh in our sanitary scales.

Tropical diseases enjoy a well deserved universal prestige. Huge quantities of money have been allotted to them because their eradication suited purposes of economic development and colonization. The truth is that if the same generosity and aggressiveness had been deployed against syphilis, for example, the situation would now be different. The same happens with the former as with cattle diseases. Even in our country there is always money to fight foot and mouth disease or anthrax, but not always for human problems. This state of affairs induced Theobald Smith to say that farmers are more interested in the health of their cattle than in that of their children, which statement was no doubt a sign of momentary despair.

With apparent pride we Chileans claim to have one of the highest infant mortality rates in the world. We actually appear on the list after Malta and Gozo and Burma which cannot be taken into account (fig. 3). These high rates can be explained only if we accept that among us a deficient public health service exists side by side with a good organization and much honesty in the recording and publication of statistical data. As a matter of fact, there have been eleven censuses from 1835 to 1940. Long before the whole of the United States was included in the registration area, we knew of all deaths in our country, since it is forbidden to bury a corpse without exhibiting a death certificate.[8] Although still defective, birth registration is stimulated by the social laws which grant family allowances according to the number of children. Because medical services attend a considerable proportion of the population, we have fairly reliable information on venereal diseases, tuberculosis and heart diseases, that is, those within the province of our social laws.

Incidentally, we may point out that Chile is the pathologist's paradise. The approximately thirty thousand hospital beds that we have are dependent on a central authority, and all patients who die in them are subjected to autopsy. For this regulation to be waived a judge's permission must be obtained, which time does not always allow. Foreign doctors who visit us are always surprised by the number of autopsies and the ample possibilities for holding joint meetings and investigations on clinical and pathological subjects.

Do not believe that I am being carried away by national sentiments. There is no plausible reason for Chile, with a homogenous race and benign climate, to have a higher infant mortality rate than some of her neighboring countries that do not enjoy these privileges and are not more civilized. In some of these, infant mortality has been halved just because the government has changed hands and much of the information published is based on estimations or surveys undertaken at a given moment. It is amusing sometimes to read the commentaries of some of those terribly lofty English newspapers on the high number of crimes or passion tragedies that there are in Chile. As a matter of fact, we are not more criminal and probably not more passionate than other American nations, but we record our data and are not self conscious about publishing them.

Nevertheless it cannot be denied that our infant mortality rate was excessive, so much so that it came down considerably within the last few years under the influence of rational measures: from 226.4 in 1936 to 142.8 in 1946.[9a] An amendment introduced in social legislation in 1937 allows for the care of working women and workmen's wives during pregnancy and childbirth, and of their children during their first two years of life. Thus, 25 per cent of the children of this age group and 16 per cent of the pregnant women are under supervision. This control includes medical attention as well as a supply of milk. For the specialists an interesting detail is here pointed out. The causes of infant mortality are ordinarily classified in three large groups: the enteric infections of the summer, infections of the respiratory tract in winter and, thirdly, causes peculiar to newborn infants. In countries with bad sanitary conditions and high infant mortality rates, enteric infections predominate and are the first to be reduced when measures are taken. The infections of the respiratory tract follow, and structural causes are prone to increase in proportion and absolutely under the influence of modern living, childbirth with medical interference, obstetric interventions and lying-in hospitals. In accordance with the general principle, enteric infections have predominated in Chile, but the descent has been due mainly to causes peculiar to newborn infants.

Chile has a very high rate of illegitimacy, around 30 per cent; the rate of Caracas is, however, 60 per cent. This naturally affects the infant mortality rate, but not so much as it would in the United States and Western Europe, because among us it is not necessarily the consequence of loose morals. Many couples, joined in a stable monogamous relationship, simply do not bother to get married. That influence may also be exaggerated because among babies born out of wedlock there is a predominance of first-born infants which are the ones most likely to die. Our families are still large, and the seventh or eighth child runs a worse risk. This fertility implies that women begin to procreate earlier and finish later than in the United States, and in the extreme ages the risks are noticeably greater.

Our tuberculosis mortality rate is shamefully high and holds the second place among all causes of death. Although we have more beds per person than the United States has,[10] these are insufficient compared with the number of patients.[11] The rule holds for all Latin America, probably with the single exception of Venezuela. To protect the tuberculosis patients we have a special set of laws, according to which all our workers and employees who suffer from curable tuberculosis have a right to rest, receiving full salary, until the disease has been cured or become incurable. The sums of money that this work and others entail are insufficient for the necessities but large for our economic possibilities. Their effect is just beginning to be felt in the mortality curves that have remained high and horizontal for the last forty years. It may be due to the fact that they have been carried out during the epidemic phase, that is to say, when the infection was propagated profusely owing to industrialization. The mortality curve has a cyclic tendency, with an oscillation period of about thirteen years, a commentary on which does not belong here.[11]

If in France Mademoiselle Marie Petit marries Monsieur Jean Simon she becomes Mme Marie Simon née Petit. If in the United States Miss Mary Smith marries Mr. Peter Jones she becomes Mrs. Peter Jones or Mrs. Mary Jones or Mrs. Mary Smith Jones. If señorita María Pérez marries Juan Torres she becomes señora María Pérez *de* Torres. A somewhat loose interpretation of these facts may allow us to surmise that the French and American customs wanted the personality of the woman to merge with that of her husband and form a new one. The Spanish custom, on the contrary, seems to want the woman to become merely a possession of the man. Keep in mind this symbol to understand the problem of our venereal diseases, which are also prevalent and will not diminish very noticeably unless we take firm steps to put an end to prostitution. If you say something of this sort in your countries, your audience will shrug their shoulders and take you for a dreamer.

[10] In 1940, there were in Chile 0.9 free beds per thousand inhabitants and in the United States 0.63 free and 0.76 between free and paid beds.

[11] Romero, H., and Moroder, J.: La población y el medico: Los recursos económicos de la colectividad; VII. Lucha contra la tuberculosis, Prev. Soc. **14**: 40-54 (Jan.-March) 1947.

In 1940 Chile organized the National Service against Venereal Diseases, pooling the resources of the different institutions and establishing a uniform plan. The first obstacle to be overcome was the individualistic tendency of the doctors, who would rather rely on their own experience than on the most overwhelming statistical data. The program produced immediate effects on morbidity rates, especially on new infections. Moreover, Chile, which is the only country south of the Rio Grande that prepares neoarsphenamine and oxophenarsine hydrochloride for its own consumption and for exportation, was the second country after the United States to accumulate 1,000 cases of massive treatment.

In 1945 the prevalence of syphilis was similar in the United States and in Chile. Thus, the National Medical Service for Employees found 5.2 per cent of positive serologic reactions in 112,000 persons who came for their first examination. In the first 2,000,000 conscription examinations, the rate of positive reactions in the United States was 4.6: 18 per cent among whites and 24.5 per cent among Negroes. The decrease in syphilis mortality can be seen in table 2.

TABLE 3.—*Expectation of Life at Birth*

| Area | Period | Complete Expectation of Life at Birth, Yr. |
|---|---|---|
| Chile | 1939-1942 | 41.8 |
| Chile | 1929-1932 | 40.6 |
| Chile | 1919-1922 | 31.5 |
| Argentina (Buenos Aires) | 1914 | 46.4 |
| Brazil (federal district) | 1939-1940 | 43.0 |
| Brazil (São Paulo) | 1939-1940 | 50.1 |
| Colombia (7 departments) | 1939-1941 | 46.3 |
| Costa Rica | 1927 | 40.7 |
| Mexico | 1929-1933 | 37.2 |
| Peru (Lima) | 1933-1935 | 39.0 |
| Venezuela (Caracas) | 1937-1939 | 44.2 |
| United States | 1939-1941 | 63.6 |
| England and Wales | 1937 | 62.3 |
| France | 1933-1938 | 58.8 |
| Germany | 1932-1934 | 61.3 |
| Spain | 1930-1931 | 51.2 |
| Russia (Europe) | 1926-1927 | 44.4 |

All the infectious diseases together do not weigh heavily on the sanitary scales[12] and, as everywhere, have diminished noticeably. If tuberculosis is included among them it naturally occupies an increasingly larger proportion, well over 50 per cent. In the United States as well as in Australia and New Zealand, for instance, national groups brought with them from Europe their genealogic lines and immunologic experience. They are what we would call Europe overseas, but we, a new race, suffered catastrophic epidemics. We had cholera, plague, smallpox and, recently, meningococcic meningitis. Thanks to compulsory vaccination, smallpox has disappeared completely, although it exists in the three surrounding countries. Typhus is virtually dominated and can never again reach epidemic proportions, because we have a good control service and experience in DDT (dichlorodiphenyltrichloroethane) application. The meningitis epidemic of 1941-1942 had a comparatively low fatality (10 per cent), owing to the rational use of sulfonamide drugs. As in other countries, the incidence of infections of the nervous system has begun to increase, such as encephalitis, poliomyelitis, and polineuritis.

As infant mortality and mortality rate for infectious diseases and for all causes diminish, life expectancy increases (table 3). Between 1920 and 1940 we gained 10.3 years: as a matter of fact, life expectancy at birth went up from 31.5 to 41.8 years.[6]

Because our life expectancy is low, we have that young population we spoke of. On the other hand, the probabilities of survival at 70 years of age are almost the same as in the United States and have hardly changed in one country and the other ever since we first had reliable information. Therefore, it is preposterous to say that in Chile, or in South America as a whole, people do not attain advanced ages. Indeed, those who manage to avoid the causes of the pathetically high rates of infant mortality, tuberculosis in adult age and other causes of death, and reach a mature age, have then even better probabilities of survival than have inhabitants of North America.

In 1940, our life expectancy was smaller than in the United States in 1900. We may well imagine that our curve will imitate that of the United States in some past period. Warren S. Thompson has repeatedly pointed out the demographic analogy between countries and said that "the past" of one may be "the future" of another.

There are other problems occupying a foremost position in our minds. The first of these is public health education, understood not as a specialty but as the embodiment of knowledge concerning health in the average education. Our expression seems more adequate: education for health (*educación para la salud*). It should be incorporated in high school education so that it reaches politicians. Until our citizen definitely gives up completely the fatalistic attitude and understands that it is possible to defend and promote health, our work will not be very rewarding.

It could be said that we must first improve the production and distribution of food stuffs. However, it seems much more urgent that the people learn how to eat. This is not a country for the gourmet, who may find more satisfaction in Argentine, Perú, Mexico, Chile and other countries; but the common diet is incomparably more rational than in any other part of America. Usually our people eat according to their prejudices and traditional habits. The practical application of modern knowledge in this matter would pay better dividends than any other activity.

There is plenty to be done concerning the housing problem. Much could be told of how our colonial towns are being modernized and about the patios disappearing, while small skyscrapers and apartment houses are being built. But these are essentially national affairs, and our sanitary functions consist mainly in convincing the authorities that neither civilization nor health is possible without acceptable dwelling places, that a large proportion of the citizens cannot build their own houses and that others cannot even pay to live in them, whether they buy or rent them.

Although a high proportion of the population has drinking water and adequate means for excreta disposal, our mortality rates for enteric infections are still too high. We have endeavored to reduce them by means of a permanent immunization campaign, which means, as we say, bread for today and hunger for tomorrow. Foreigners who visit us or come to stay among us are strongly advised to get vaccinated, as they run far greater risks than we do. Recently efforts have been made to improve food control, diminish the number of flies and educate the population, measures that are making their influence felt. The considerable success of the Division of Health and Sanitation of the Institute of Inter American Affairs in our countries is largely due to the fact that they have contributed toward the progress of our water supplies and sewage systems. It would have been greater if they had not been so reluctant to bury money in the ground, an investment that is invisible but which produces handsome revenues.

COMMENT

Public health is today a science interesting and useful enough to attract persons of high quality. The mere enunciation of its achievements, its projects and unsolved problems could well be the subject of long discussions which would surely interest any cultured physician. For success, we need many more specialists, and to form them we have our School of Public Health, the achievements of which will make an attractive story. As just one example of what modern policy can produce, we may say that in one of our health units, founded and run with the help of the Rockefeller Foundation, the mortality rate among children under control is considerably lower and similar, or parallel, to that of New York. The foregoing account should lead one to the conclusion that Chile is a young country the characteristics of which correspond to a certain phase of demographic evolution and the sanitary conditions of which could be considerably improved by our taking advantage of foreign experience and applying it to our conditions and peculiarities. Money does not matter, because when well spent it can never be wasted. Besides, these expenses are self liquidating. On the contrary, it is important to convince both the politicians and the people that public health is no longer a mere expression of common sense but that it requires knowledge and technic. Doctors can help toward this end.

The reader will also have concluded that Latin America is a kaleidoscope. Large parts of it have a common origin, a mixture in different proportions of similar races and languages. Under the influence of geographic conditions and after over a century of independent life, they have become very much differentiated. Men of good will in our country believe that they should draw more closely together, among themselves and with Anglo-Saxon America. This objective will be considerably enhanced by the transportation and communication facilities and may be perfected by means of mutual knowledge and understanding. To this purpose we have devoted an enormous amount of time and effort.

---

**Use of Anticoagulants in Coronary Thrombosis.**—On the basis of data compiled from 800 cases of coronary occlusion with myocardial infarction, it is concluded that patients treated with anticoagulant therapy in addition to the conventional forms of therapy experience a death rate and incidence of thromboembolic complications during the first six weeks period following an attack markedly lower than those experienced by patients treated solely by conventional methods. Anticoagulant therapy should be used in all cases of coronary thrombosis with myocardial infarction unless a definite contraindication exists. In the absence of hemorrhagic conditions the hazards from hemorrhage are not sufficient to contraindicate the use of anticoagulants in coronary occlusion, provided that there are facilities for adequate laboratory and clinical control.—From an address by Dr. Irving S. Wright delivered before the Graduate Fortnight of the New York Academy of Medicine, Oct. 5, 1948.

## SPONTANEOUS RUPTURE OF THE STOMACH

### Report of a Case

D. GORDON BURKET, M.D.
Altoona, Pa.

Spontaneous rupture of the stomach is a catastrophe which many surgeons and many more practitioners of other branches of medicine would not include among the possibilities if they were called on to attend a patient presenting the typical picture of this calamity. Of the 30 or more cases reported in the literature, there was not 1 case in which the condition was diagnosed before operation or autopsy; yet the picture is distinctiveand not presented by any other abdominal emergency. The reason for failure to name the accident at fault is undoubtedly lack of knowledge that it can occur. It is so rare that most practitioners have never heard of it and therefore do not list it as one of the possibilities when presented with the problem of diagnosis.

This case is presented not only as a contribution to the knowledge of the causes and characteristics of the condition, but also in the hope that some reader may remember the possibility if he is called on for treatment.

The following case is cited as a typical example of the picture presented by spontaneous rupture of the stomach, and also happens to be a case with the commonest antecedent train of events.

REPORT OF A CASE

A nun, aged 61, in the hospital with which I am associated, was accustomed to taking a dose of citrate of magnesia every few days to relieve abdominal discomfort which she attributed to chronic constipation. At 3 p.m. on May 7, 1946, she took one bottle of citrate of magnesia, and about 7:30 p.m., because she still had discomfort, she went to the hospital pharmacy and asked the pharmacist's assistant for sodium bicarbonate. She was given about a tablespoonful in an unusually large glass of water. Immediately after drinking it, she collapsed on the floor in severe agony, she became cyanotic and dyspneic; the skin became cold and clammy and the pulse imperceptible. The intern was called and noted severe abdominal tenderness and rigidity. The abdomen was silent. Her condition improved a little in that the pulse became barely perceptible, and she was scheduled for operation within two or three hours.

However, her condition became rapidly worse, continuing while she was on the operating table and before any anesthetic was administered, and she became unconscious. Decision was made to operate on account of the almost certain presence of a visceral perforation. Rupture of the stomach was not even considered, but the preoperative diagnosis was "perforation of a hollow viscus."

Some excess of fluid with some flakes of fibrin floated in it was seen, and the serosa was injected. Not until the lesser peritoneal sac was opened, however, was the diagnosis made. Here was found foamy white material, which was undoubtedly sodium bicarbonate with enclosed fine gas bubbles which boiled out through the incision in the gastrohepatic omentum. Chewed undigested food was delivered from the lesser peritoneal cavity by the handful. Meat and grapefruit particles were recognized. The rent in the stomach, about 5 cm. in length, was seen running longitudinally at the midportion of the lesser curvature. No evidence of disease of any layer of the wall was observed.

The laceration in the stomach was sutured, and, while the abdominal wound was being closed, the condition of the patient became rapidly worse, in spite of the administration of 600 cc. of plasma. Death ensued before the closure was completed.

COMMENT

The degree of shock, the intensity of the prostration and the suddenness of onset are dramatic and not simulated by any other type of perforation, not even by pancreatic necrosis, there being not quite the abrupt precipitation of these physical signs in the latter condition. Ruptured ulcer, aside from the probability of an antecedent history of ulcer, does not give the degree of severity of symptoms by a wide margin. Any case with the history of ingestion of sodium bicarbonate followed by sudden abdominal pain and severe and dramatic onset of shock and prostration should be immediately considered a case of spontaneous rupture of the stomach.

The condition is rapidly fatal in the vast majority of cases. In 31 cases collected by Lemmon and Paschal[1] in none was the condition diagnosed preoperatively or before autopsy. Of the 31 patients only 5 were operated on and only 2 of these recovered. Of the ones not operated on, 2 recovered spontaneously, with abscess and fistula formation.

Spontaneous rupture of the stomach in the cases reported occurred along the lesser curvature, where the weakest part of the muscular wall would seem to be found. In my case, as well as the others reported, there was no evidence of any disease of the area. The mechanism of rupture appears to be a rather abrupt release of carbon dioxide caused by the action of acid on the sodium. The acid may be hydrochloric or acids of fermentation or, as in this case, the citric acid of the cathartic. The stomach is full in all cases. It is probable that there is associated pylorospasm prompting the ingestion of the sodium bicarbonate. The patient likely has some cardiospasm or closure of the cardiac end caused by angulation also, in which case the distention of a full stomach with sodium bicarbonate is so sudden that it cannot be released quickly enough through the natural outlets.

The literature on rupture of the stomach is not voluminous. Petry reported 8 cases in 1896 and comparatively few have been reported since that time. It appears to be of rare occurrence and fortunately so.

### SUMMARY AND CONCLUSIONS

The following points can be deduced from an analysis of reported cases: Aside from trauma, rupture occurs from rapid release of gas in the stomach, a few from fermentation of gastric contents, but most from the release of carbon dioxide by the action of acids on ingested sodium bicarbonate. The stomach in this latter condition is always full. Some spasm of the pylorus and cardia probably is necessary. The shock and prostration are severe. The condition has never been diagnosed preoperatively, and the mortality rate is high.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

AUSTIN SMITH, M.D., *Secretary.*

**SULFADIAZINE** (See New and Nonofficial Remedies 1947, p. 120).

The following dosage form has been accepted:

PITMAN-MOORE, INDIANAPOLIS

**Solution Magmoid Sulfadiazine:** 30 cc., 60 cc., 360 cc. and 3.84 liter bottles. Preserved with benzoic acid 0.25 per cent.

**OLEOVITAMIN A-U.S.P.** (See New and Nonofficial Remedies 1947, p. 502).

The following dosage form has been accepted:

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

**Capsules Oleovitamin A:** Each capsule contains 25,000 U.S.P. units of vitamin A derived from fish liver oils.

**DIHYDROXY ALUMINUM AMINOACETATE** (See THE JOURNAL, July 31, 1948, p. 1226).

The following dosage form has been accepted.

EATON LABORATORIES, INC., NORWICH, N. Y.

**Tablets Aspogen:** 0.5 Gm.

## Council on Foods and Nutrition

*This paper was prepared at the request of the Council and is one of a series appearing in* THE JOURNAL. *Later the entire series will appear in book form as the Council's Handbook of Nutrition.*

JAMES R. WILSON, M.D., *Secretary.*

# IODINE IN NUTRITION

GEORGE M. CURTIS, M.D.
and
M. BEEN FERTMAN, M.D.
Columbus, Ohio

During the early years of the present decade, perhaps even in the still turbulent days of 1948, there could be seen on the highways of the Chinese province of Yunnan numbers of cretins, as well as other persons little more fortunate, displaying prominent goiters. Men and women working on the Burma Road were showing an incidence of thyroid enlargement often as high as 80 per cent.[1] Residence in the Yunnan district for as little as six months, it appears, would suffice to induce such deformity in susceptible persons.

For an understanding of this striking phenomenon, in many respects similar to the once epidemic proportion of goiter and cretinism in Berne, Switzerland, it is necessary only to remember that the Japanese were, in the early 1940's, still in control of strategic areas of China. As a consequence, the hinterland of China was cut off from its former coastal supply of salt with a high content of iodine. Not only the Yunnan area itself but also other large sections of Free China were thus forced to depend on Yunnan salt, which is very low in iodine content.[1]

This remarkable incidence of goiter in Yunnan, resultant to the military stranglehold on those areas furnishing the only supply of salt with a high iodine content, is no mere coincidence. The inverse relation between a high incidence of goiter and cretinism and the amount of iodine found in the soil of a given region, in its water, its salt and mineral deposits, and particularly in its food, has long been known. Repeatedly this observation has been supported by similar massive evidence.

Thus, it becomes necessary to appreciate the powerful role which iodine plays in human biologic processes. This element is found throughout the world in varying proportions. It occurs in minute quantities in the very air one breathes. It is dispersed in the water. It exists in the soil and in the rocks. It is present in nearly all living things, both plant and animal. Not the sea, as is popularly believed, but the earth's crust is the major storehouse of iodine.[2]

Endemic goiters are observed in great numbers among the inhabitants of those regions deficient in iodine. The highest incidences of goiter have been observed in the Alps, the Pyrenees and Himalayas, the Thames Valley in England, certain inhabited districts of New Zealand, in the region of our own Great Lakes and in the Pacific Northwest.[2b] Throughout the United States there occur varying degrees of available iodine,

[2] (a) Orr, J. B., and Leitch, I.: Iodine in Nutrition, Medical Research Council, Special Report Series No. 123, London, His Majesty's Stationery Office, 1929. *(b) McClendon, J. F.: Iodine and the Incidence of Goiter, Minneapolis, University of Minnesota Press, 1939.*

depending on local geologic conditions of the soil and waterways. A high incidence of goiter is especially noteworthy in the Central Plain of North America, where regional iodine is low. On the sea coasts, where large amounts of high iodine-containing sea foods are consumed, there is a minimum of endemic goiter.

The water of the Great Salt Lake resembles the ocean in its iodine concentration and yet, unlike the ocean, supplies neither vegetation nor fish for human consumption.[2b] Consequently, it should cause no great wonderment that the inhabitants of the Great Salt Lake area have a high incidence of goiter; for the problem of endemic goiter largely resolves itself into a consideration of the amount of mammalian iodine consumption within any given region.

Iodine is ingested essentially from the food supply and to a lesser degree from ordinary salt or from water.[2a] About 14 micrograms daily was formerly thought to represent the difference in iodine intake between [illegible] nongoitrogenous regions.[3] However, [illegible] in iodine consumption have become even less pronounced as the interstate transportation of food, drinks, vegetables, fruits and fertilizers has increased.

The amount of iodine found in the local drinking water is a frequently used measure of the iodine content of the regional soil and consequently of its fruits, grains, grasses and vegetables. It is not important as a source of nutritional iodine save in unusual circumstances.[2a] Moreover, when the country is divided into sections according to the occurrence of iodine within its waters, it will be found that where the iodine content is low, the incidence of goiter is correspondingly high. Such regions are to be found in a section extending from Oregon to the western part of Maine and from Nevada to the western part of Virginia.[2b] The Michigan studies revealed that the incidence of goiter in a given locality varies inversely with the amount of iodine found in its water.[4]

The iodine in food is the single most important factor determining the extent of endemic goiter prevalent throughout a given area. Thus, it is readily understood why Japan, though geologically low in iodine, presents an outstanding example of a goiter-free area, while Formosa, similarly depleted in iodine, has a high incidence of goiter among its population. The absence of goiter in Japan results from a Japanese taste for seaweed, which is therefore extensively imported and consumed in large quantities.[2b] Seaweed is rich in iodine content.

In South Carolina, where the vegetables are considerably higher in iodine content than those of the Northern and Western states, the incidence of goiter is low.[5] However, the interstate importation of canned foods and other food products does not, to any apparent degree, help solve the goiter problem in the North and West, for the cotton-growing and tobacco-growing South as a whole, comprising a great part of the goiter-free United States,[6] fails to produce sufficient food and feed crops even for its own needs.[6b] Canned goods must therefore be imported from sections of the country where the soil is poor in iodine.[6]

The iodine concentration of the milk produced in a given locality is another good index of endemic goiter in that region.[7] The amount of iodine which the lactating mammal consumes and then puts out in her milk, in the absence of any supplemental iodine, depends on the amount of iodine in the soil and its vegetation.[8] Likewise, the egg is dependent on the chicken for its iodine content and the chicken on the products of the "good earth." [7b]

### IODINE CONTENT OF THE HUMAN BODY

A normal man weighing 70 Kg. may be reasonably estimated to contain about 50 mg. (less than a grain) of iodine. This is equivalent to about 1 part in 1,400,000 of body substance. Iodine thus forms less than 0.00008 of 1 per cent of the total body weight. Nevertheless, every cell in the body is said to contain some iodine.[9]

### IODINE AND THE NORMAL THYROID GLAND

The thyroid gland is a principal storehouse for the iodine of the human body. Weighing ordinarily about 25 Gm. and containing about 10 mg. of iodine, it normally maintains an iodine concentration of around 40 mg. per hundred grams. It was shown long ago by Marine and Lenhart that when this concentration falls below 10 mg. per hundred grams hyperplasia ensues and goiter is likely to develop.[10]

No other organ of the mammalian body has the power of iodine concentration possessed by the thyroid gland. The whole blood iodine averages less than 1 part in 25,000,000, while the thyroid gland normally contains approximately 1 part in 2,500. This indicates that the thyroid gland can concentrate the iodine it obtains from the blood by a factor of at least 10,000.

Within the colloid in the alveoli of the thyroid gland iodine is stored in a combined form with the amino acids, diiodotyrosine and thyroxine. These contain, respectively, 59 and 65 per cent iodine. The accepted facts of thyroid function indicate that iodine is selectively absorbed by the active thyroid gland. Furthermore, in some measure the glandular function is regulated by its iodine content. Studies with radioactive iodine have shown that ingested iodine is quickly brought to the gland by the blood stream and rapidly converted by the thyroid cells into complex organic compounds. Within a matter of only a few hours these organic iodine compounds, just manufactured by the cellular activity of the thyroid gland, may return to the circulation.[11]

A basic peculiarity of this regulating gland, first observed before the turn of the century,[12] is its low iodine concentration when its weight is high and, inversely, a high iodine concentration when its weight

is low.[13] Moreover, the thyroid iodine content is low with either a high incidence of nodule formation or a high percentage of epithelial proliferation. It is low with increased height of the follicular epithelium of the thyroid gland, lymphocytic infiltration and with the occurrence of degenerative changes.[13b]

The iodine which a person absorbs from his daily food is the principal factor which determines the iodine content of the thyroid gland and overshadows other factors, such as species, age and sex. Small differences in the local food supply of iodine are reflected in the iodine content of the gland.[2a]

Since iodine intake is so largely dependent on the soil and consequently on plant iodine, the thyroid iodine concentration varies with the geographic distribution of iodine. Thus, in nongoitrogenous Texas the fat-free dried thyroid contains 6 mg. of iodine per gram, whereas in goitrogenous North Dakota it contains only 3.2 mg. per gram.[14] There are seasonal variations in the amount of iodine found in the thyroid gland,[13b] but these may be attributed to seasonal variations of the iodine available in the soils and foodstuffs.

## IODINE AND THE PATHOLOGIC THYROID GLAND

The ultimate cause of endemic goiter and its sequelae is not clear. The immediate cause is a deficiency of iodine, an element necessary in the production of the thyroid hormone with its high content of iodine. This iodine deficiency may be absolute, as in areas where the iodine intake is subnormal, or the deficiency may be relative.[15] Thus, iodine deficiency may ensue, even with a normally adequate iodine intake, whenever gastrointestinal absorption is inadequate. Other uncompensated circumstances, by interfering with the normal destination and metabolism of iodine, or by increasing the demand for this element, have the same end result. Infectious processes, the ingestion of toxic substances or of certain drugs and a diet high in calcium are among the known offenders. The physiologic stress of puberty, of pregnancy and of lactation increases the need for thyroid secretion. When these increased needs are met with an increased supply, resultant pathologic change is forestalled, as can be demonstrated in the thyroid histologic observations in pregnant animals fed sufficient supplemental iodine.[16]

The microscopic changes in the thyroid gland closely parallel the chemical observations.[13b] Baumann and Roos [17] and also Oswald [18] were the first to observe that if iodine is withheld compensatory hypertrophy of the thyroid occurs. They noted that the iodine content of the thyroid is proportional to the amount of colloid present and that in colloid goiter the concentration of iodine is significantly below that seen in the normal gland. When normal or goitrous thyroid glands obtained from iodine-deficient regions are compared with other normal or goitrous glands, it is observed that the thyroids from the goitrogenous regions are the largest and have the highest incidence of nodule formation, the smallest follicular size and the lowest iodine content.[13b]

If iodine is administered to a person who has either a normal thyroid gland or even colloid goiter, the iodine content of the gland increases with no notable change in its structure. When iodine is withheld from the experimental animal, the iodine content of the gland gradually decreases, and in the wake of thyroid lobectomy there will be hyperplasia of the remaining lobe. The administration of iodine prevents this sequence of events both prior to and following lobectomy.[10]

Remington has shown that it is possible to produce enlarged and hyperplastic thyroid glands in young rats fed for five weeks on a diet extremely low in iodine. The addition of iodine to their diet prevents the development of goiter. However, storage of iodine is insufficient in rats fed this supplement during their first four weeks of life, since it does not prevent the development of goiter when iodine is later withdrawn. Varying the calcium content of the ration given the rats, or its calcium-phosphorus ratio, does not affect the degree of goiter produced. Likewise, the omission or addition of vitamin D is of no consequence.[19]

## IODINE IN THE EXTRATHYROID TISSUES AND BODY FLUIDS

Iodine is present in organs other than the thyroid gland. It is also found in varying concentration in other body tissues and in the various body fluids. Its role there is less clearly understood. Of the total iodine content of the human body about one half can be assigned to the muscles, one fifth to the thyroid, one tenth to the skin and one seventeenth to the bones.[20]

Because of the close interrelationship of the other endocrines with the thyroid gland, their iodine content becomes even of practical interest. There is some question whether they actually exceed the nonendocrine tissues in iodine concentration. Certain studies indicate that they do.[21] More recent work on mammalian tissue iodine [13b] and on the iodine content of normal human tissues [22] was not confirmatory. Moreover, the "master gland," the pituitary, which bears a reciprocal relation to the thyroid, so well appreciated, has a low iodine content. This is similarly true of the central nervous system itself.[23]

Considerable importance has been attached to the role played by the liver with respect to iodine.[24] Nevertheless, its actual function in this regard is still an enigma. The conviction that this significant organ, which affects so many of the body's vital activities, also exerts an influence on the metabolism of iodine, arises from various experimental and clinical observations. Thus, bile is consistently high in iodine content,[23] and except for the thyroid and hair contains, in fact, the highest iodine concentration in the human body.[22] Moreover, elevation of the blood iodine, occasionally to a considerable

degree, has been observed in patients with hepatic damage and in those with biliary tract disease.[24b] Recent investigation suggests a possible relationship of these phenomena to a newly found "antithyrotoxic" factor in liver, which presumably is a direct antagonist to the usual action of the thyroid hormone.[25]

The amount of iodine in the blood has for many years merited special consideration. It is an index of thyroid function and of iodine metabolism. It is a rough measure of the release of the thyroid hormone and of its rate of breakdown within the body after it has completed its function. With radioactive tracer methods, this significance has become even more clear. With improving technics in the fractionation of the blood and plasma iodine, means of distinguishing the circulating thyroid hormone from its breakdown products are emerging.[26] Meanwhile studies of the whole blood iodine and particularly of the protein-bound fraction serve along with determinations of basal metabolic rate to differentiate the various thyroid diseases from each other and to distinguish them from normal and nonthyroid clinical states.

Human blood normally maintains a fairly constant level of iodine. Fractionation studies reveal that about one fourth of this presumably represents the circulating thyroid hormone.[27] The other three fourths, consequently, would include the iodine of nutrition together with products of the breakdown of the thyroid hormone with its high content of iodine.

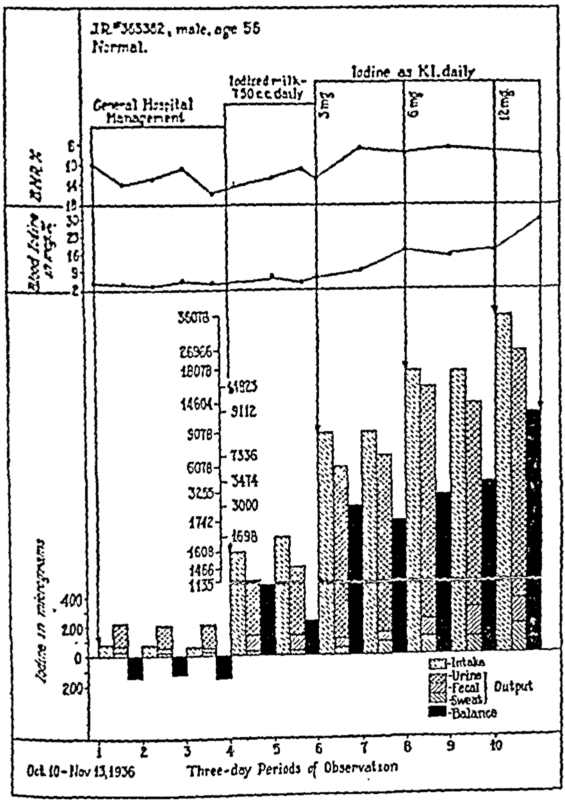

Fig. 1.—Chart showing levels in a normal subject for three day periods of observation.

Various values, ranging from 3 to 20 micrograms per hundred cubic centimeters, have been ascribed by different investigators to the normal iodine level in whole blood.[28] These vary with the method of iodine determination and the geographic area, as well as with certain physiologic factors. The blood iodine is significantly increased in pregnancy, in parturition and in toxic nodular and exophthalmic goiter (fig. 3), as well as in certain nonthyroid diseases.[29] Increased blood iodine levels observed in toxic nodular and exophthalmic goiter may be due, in part, to iodine medication, for the administration of iodine in all forms increases the circulating iodine in whole blood (fig. 1).[30]

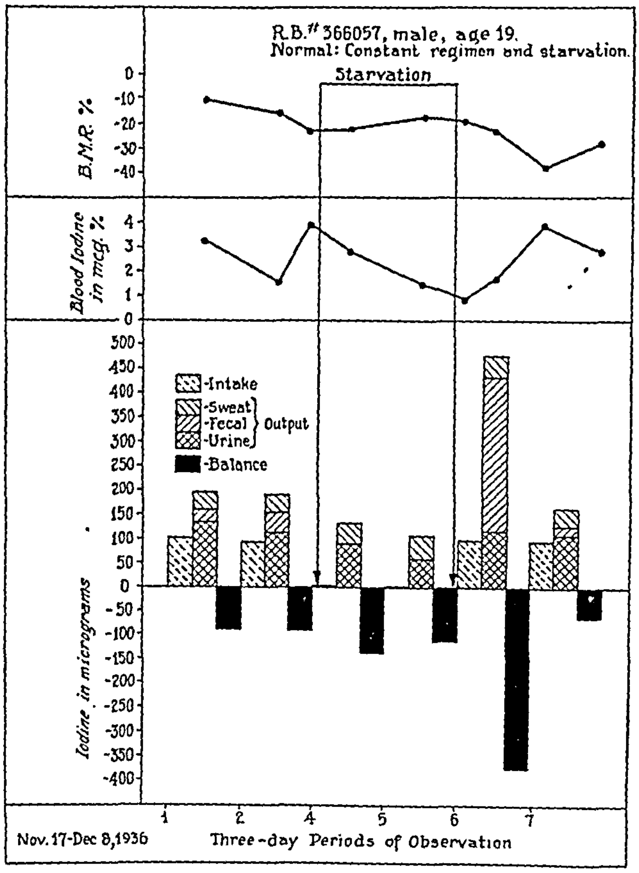

Fig. 2.—Chart showing levels in a normal subject during a constant regimen and starvation in three day periods of observation.

In hypothyroidism, the iodine in whole blood is often within normal limits.[29b] Nevertheless, the acetone-insoluble fraction, which presumably contains the circulating thyroid hormone, has an average value of about one-half normal.[27a] In nontoxic nodular goiter, this fraction may show an increase over normal [26] when the whole blood iodine does not.[29b]

The iodine concentration in the blood varies; however, it maintains a more constant level than the iodine in the thyroid.[15] The blood iodine does not always increase or decrease along with the basal metabolic rate.[31] The latter is less exclusively controlled by the thyroid gland than the circulating iodine and is, in fact, the resultant of a number of different metabolic processes. However, there is a significant correlation between the blood iodine and the basal metabolic rate in thyroid disease, noted particularly in those goitrous conditions associated with hyperthyroidism.[31b] as well as in nontoxic nodular goiter.[32]

Thyroidectomy, in human beings or in experimental animals, exerts an important effect on the blood iodine. Immediately following total thyroidectomy there is a transient increase in the blood iodine, which persists for about thirty-six hours. Following total thyroidectomy the blood iodine decreases to about one-third normal.[33]

The urinary iodine is another measure of iodine metabolism. Under maintained basal conditions, together with a monotonous diet low in iodine, the normal adult excretes a surprisingly constant amount of iodine in the urine [34] (figs. 1 and 2). There is, however, geographic variation. The urinary iodine is higher in sea coastal regions than inland regions.[15] It is higher in the nongoitrogenous than in goitrogenous areas, as illustrated by the contrasting range in iodine excretion of 72 to 343 micrograms a day observed in five nongoitrogenous regions and of 27 to 64 micrograms a day in five goitrogenous districts. The average twenty-four hour urinary iodine excretion by normal adults in Central Ohio, a region of moderate endemic goiter, is 51 micrograms.[35]

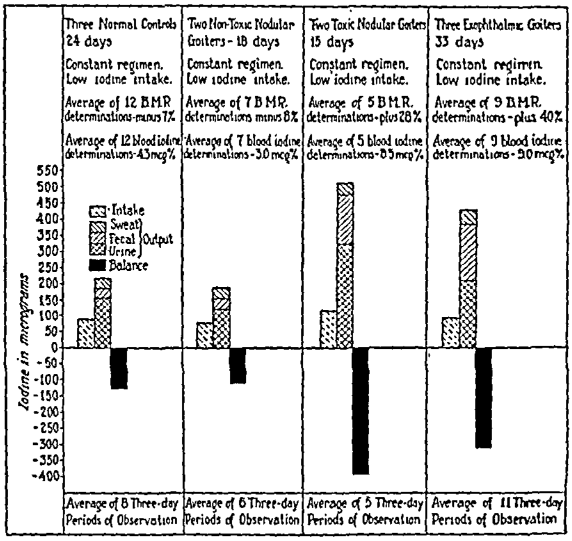

Fig. 3.—Chart showing levels seen in three day periods of observation for normal subjects and patients with various types of goitrous conditions.

Several factors tend to increase the amount of iodine lost in the urine. These include hyperthyroidism (fig. 3),[36] menstruation,[37] pregnancy,[38] surgical treatment [39] and the administration of iodine in nearly all forms (fig. 1).[40] On the other hand, fasting decreases the urinary excretion of iodine (fig. 2).[40b] The decrease is less when the fasting is preceded by an iodine-rich diet.[30c]

Iodine is also present in other body fluids. It has been demonstrated in the lymph, in cerebrospinal fluid, in perspiration (fig. 3), in chyle, in ascitic fluid, in pleural exudates and in milk. In milk it plays the important role of supplying the needed iodine to the growing infant. This iodine is lost at the expense of the mother's iodine stores [8b] and should be replaced, to maintain the health both of the child and of its mother. If iodine feeding is essential under normal conditions of stress and strain, then it is twice as important to the woman who bears a developing fetus or to the lactating mammal. The loss of iodine in milk results in depletion of the mother's iodine reserve with an ensuing negative iodine balance.[40b] This loss should be compensated for by a sufficiently large iodine reserve, previously built up, or by an increased iodine intake.[41] As iodine is administered to the mother, a greater proportion of this substance will be secreted in the milk.[42]

### IODINE AND THE PREVENTION OF GOITER

Fortunate was the empiricism which led the ancients to use burnt sponge or seaweed in the treatment of goiter. Iodine was unknown. It was not until 1811 that iodine was accidentally discovered by Courtois as a by-product resulting from the use of seaweed ash in preparing war materials for Napoleon. Within a few years Sir Humphrey Davy had isolated iodine from sponges, seaweed and other forms of marine life. Then followed a fruitful century of clinical investigation, extending from Straub of Berne to Plummer of Rochester, and of fundamental experimental researches, dating from Boussingault of Paris through Chatin, Baumann, Kendall, Marine, von Fellenberg and others to Harington of London.

Today iodine prophylaxis against goiter is widely recognized, while iodized salt is used throughout the entire United States. The extensive and increasing popularity of the use of iodized salt started from the original experiments conducted in Akron, Ohio.

Marine and Kimball's significant studies on the prevention of goiter were made on a large group of school girls.[43] About one half voluntarily received 200 mg. of sodium iodide daily for a period of two weeks each spring and fall. Among almost 4,500 girls who showed no evidence of goiter at the time the experiment was instituted, in 21.5 per cent of those without iodine supplements, and, on the other hand, in only 0.2 per cent of those who received iodine, enlarged thyroid glands developed during the two and one-half years of observation.

More than 2,000 of the Akron school girls showed an initial thyroid enlargement. In as many as 65.4 per cent of those receiving iodine, there occurred a reduction in the size of the thyroid gland at the end of one year. Only 13.8 per cent of the untreated girls showed any diminution in the size of their goiters. This same study revealed that goiter is most likely to develop during fetal life, during puberty and during pregnancy.[43]

The character and results of the Ohio demonstration stimulated similar efforts throughout the world, particularly in Switzerland, Austria and Germany. Iodine prophylaxis in Switzerland brought the steady decline of cretinism, so important an economic factor to the Swiss. Until 1922 every other newborn infant in the Canton of Appenzell began life with an enlarged thyroid gland. With the institution of iodized salt, this morbidity among newborn infants became nearly legend. Moreover, as a result of the efforts of the Swiss Goiter Commission, the use of iodized salt in the Canton of Vaud reduced the community's total goiter incidence from 77 to 21 per cent in fifteen years.[44]

The results of the incorporation of iodine in the salt consumed in the state of Michigan were likewise convincing. In 1924 common salt iodized to contain 0.02 per cent of sodium iodide was introduced by the Iodized Salt Committee of the Michigan State Medical Society in cooperation with the State Board of Health. From that year on to 1935 there ensued a 75 to 90 per cent decline in the incidence of goiter in those counties using the iodized salt.[4b] The number of goiter operations in seven large hospitals in Southern Michigan dropped from 1,452 in 1927 to 591 in 1933.[45] There was a 60 per cent decrease in the number of goiter operations performed as compared with the 17 per cent decrease in all operations during the corresponding depression years.

Iodine supplementally administered in the form of iodized salt has repeatedly proved beneficial in the prevention of endemic goiter. Its curative effect, however, depends on the character of the goiter, as well as on the age of the patient at the time iodine therapy is instituted. While iodine administration is of value to patients with colloid goiter,[2a] little beneficial change may be expected in older patients with goiters of long standing in which there are extensive pathologic alterations, such as hemorrhage with resultant cyst formation, calcification, vascular degenerative changes and old nodular formations.[30a,b]

Ordinarily microscopic changes will occur in hyperplastic thyroid glands after the administration of supplemental iodine. Rapid involution of existing hyperplasia may be induced. Moreover, glandular hyperplasia of the residual tissue, even after extirpation of as much as three fourths of the thyroid, can be prevented by the administration of sufficient iodine. It has been observed that a hyperplastic gland cannot revert to the colloid state without the presence of a necessary minimum of iodine.[10]

The efficacy of iodine prophylaxis is greater the earlier it is applied and decreases after puberty.[2a] Consequently it would seem wisest to commence prophylaxis even before the time of conception and to maintain it throughout the pregnancy. It should be continued during childhood and particularly through the menarche. This can be adequately accomplished in iodine-deficient regions where goiter is frequent by the continued use of iodized salt.

Subsequent to the nearly worldwide preventive use of iodine, a general decline in the incidence of goiter occurred, particularly in Switzerland, in Austria, Germany, Northern Italy, the United States, England, New Zealand, in Poland, Rumania and Latvia.[15] A turnabout in the incidence of goiter in those countries ravaged by war may be anticipated, along with other nutritional deficiency diseases now rampant in Europe and in Asia. As iodine deficiency develops, the incidence of endemic goiter will increase.

Despite almost worldwide favorable results with iodine prophylaxis, thus again substantiating the basic theory on which it rests, objections have been repeatedly raised, in the earlier years abroad and more recently in the United States, to the preventive use of supplemental iodine. Principal among these objections has been the conjectured harm which iodine might inflict on persons with overactive thyroid glands. Moreover, there has been concern that a simple nodular enlargement of the thyroid might thus be stimulated so that a "toxic" or hyperfunctioning type of condition developed.

The basis of this fear of "jodbasedow," or iodine-induced hyperthyroidism, arose as early as 1820, when Coindet treated his patients with excessive amounts of iodine.[46] This fear has continued through the years, almost paralleling the subsequent progress and repeated successes of iodine prophylaxis. It has been a natural reaction to the dangers inherent in pioneering a drug the action of which was not fully understood. More recent exponents of the theory behind "jodbasedow" were Theodore Kocher and his successor Fritz de Quervain. In 1904 Kocher reported that hyperthyroidism may develop in patients with nodular forms of goiter treated with iodine. In 1910 he wrote of the untoward effects of iodine in toxic diffuse goiter.[47] In 1933 de Quervain listed 33 cases of "jodbasedow" observed during a period of nine years.[48]

Convincing proof is lacking that iodine-induced hyperthyroidism ordinarily or even commonly results from the administration of increased amounts of iodine to goitrous patients. On the other hand, evidence is extensive that supplemental iodine is almost universally beneficial in the prevention of endemic goiter. Kimball observed that only 4 per cent of patients with "adenomas" had hyperthyroidism after the use of iodized salt, whereas 56 per cent of those with goitrous "adenomas" who used no iodized salt or any other form of iodine medication later manifested evidence of increased thyroid activity.[49]

In current medical practice there is ordinarily little hesitancy in prescribing relatively large amounts of iodide on specific indications: syphilis, hypertension or bronchiectasis, for example, without any special regard to the thyroid and its activity. Demonstrably harmful effects as a result of increased thyroid function are not

expected and are rarely encountered. At most there ensues, from the administration of iodides, and then only on occasion, the symptoms of iodism, ranging from mild coryza or moderate acne to severe dermatitis accompanied even with a high temperature.[30c]

No ill results should be anticipated from the widespread use of iodides in the minute concentration in which they occur in iodized salts; there have been no reports of iodism induced by the consumption of diets rich in iodine-containing foods in the annals of medicine.[50]

### IODINE IN THE GENERAL HEALTH OF HUMAN BEINGS AND DOMESTIC ANIMALS

Iodine, forming 65 per cent of the thyroid hormone, is a nutritional necessity for the general health of human beings and domestic animals. General health problems ensuing from iodine deficiency are in great part the result of the importance of iodine in maintaining normal thyroid function.

Sufficient iodine is requisite for normal growth. It is well known that thyroid substance plays this role. As early as 1895 it was demonstrated that growth may be induced even in certain cretins by the administration of dried thyroid. Similar results have since been obtained in children of iodine-deficient areas, who have failed to grow normally because of lesser degrees of hypothyroidism.[51] Topper and Cohen recorded that the administration of thyroid to normal children, as well as to children presenting evidence of hypothyroidism, resulted in definite growth acceleration in both groups.[52]

The role of iodine in growth has also been demonstrated. Thus, Swiss statistics show that boys receiving supplemental iodine grew in a year on the average 7 mm. more than untreated boys and put on 200 Gm. more of weight. The mean weight at birth of infants whose mothers were receiving iodized salt was 100 Gm. greater than that of control infants.[2a] Hunziker observed that the average height of Swiss recruits was significantly greater from 1908 to 1912 than during the period from 1884 to 1891. He concluded that supplemental iodine was partly responsible for this increase in stature. Moreover, he found the average height of recruits from sections with a low incidence of goiter exceeded that of recruits from the more goitrogenous areas.[53]

Feeding milk with an increased iodine content to children living in a region of high goiter incidence resulted in more rapid and regular growth and development. Children with debility or those who revealed slow development, failure to gain weight or retarded growth showed subsequent steady improvement.[54] Administration of optimal amounts of iodine to nursing animals accelerated the rate of growth and weight of their young.[55] Direct iodine administration to the young was likewise beneficial.[56]

The favorable effect of iodine on the growth of vertebrates may be direct or indirect. It appears more likely that iodine acts indirectly by supplying the necessary constituent for normal thyroid secretion, thus permitting the gland to exert its usual function.

Besides its importance in growth, iodine also plays a role in human and animal fertility[57] and even in lactation.[58] A preliminary report on the effect of iodine on failing lactation indicates that this condition is due not to a defective thyroid gland but to a deficient intake of iodine. As in similar experiments with animals,[57] all mothers responded with increased output of breast milk.[58b]

Breeding difficulties among animals long existed in varying degrees throughout the goiter areas of the United States, until the prophylactic use of iodine became widespread as a means of combating this problem.[59]

As early as 1907 iodine-containing salts were fed to Michigan sheep in order to prevent the high mortality rate ordinarily occurring among newborn lambs.[59d] In 1916 Montana, faced with a high mortality rate among its live stock, as well as with the development of goiter and underfunctioning thyroids, instituted similar treatment with success.[59e] Since the introduction of iodized salt at the University of Wisconsin farms in 1920, there has not been an instance of goiter among the domestic animals, including sheep, swine, colts and calves.[4a]

Iodine prophylaxis of iodine deficiency disease among domestic animals, or "fetal athyrosis," as it was then designated, has spread to other states and provinces. Minnesota, North and South Dakota, Wyoming, Washington, Idaho, Southern Alberta and British Columbia have similarly used iodine preventively.

### THE HUMAN REQUIREMENT OF IODINE

The supply of iodine necessary to answer the needs of the human body should be sufficient to meet the daily losses by excretion and to maintain within the body such reserves as may be needed in the manufacture and distribution of adequate thyroid hormone. The amount of iodine intake, however, is not always equal to the physiologic needs. This is in contrast with the organism's chlorine requirement, which is more easily met because of the association of this element with the sensation of taste.

The fundamental question thus arises: How much supplemental iodine is necessary in those areas in which goiter is prevalent in order to protect the populace from the effects of iodine deficiency? Thus far, three methods have been developed in attempts to answer this question.

By the geographic method the iodine intake of the inhabitants of goiter-free areas is determined and compared with that of areas of varying degrees of goiter incidence. The difference in the amount of average iodine intake is then regarded as the amount of supplemental iodine required. According to von Fellenberg's estimate the annual iodine intake in one goitrous and one practically goiter-free area in Switzerland was

4.7 and 11.4 mg., respectively. Calculating from this, the iodine requirement would be less than 20 micrograms daily, a figure now regarded as extraordinarily low.[42c] Calculated on determinations of the average daily urinary loss of iodine (figs. 1 and 2) which is an unusually accurate barometer of the iodine intake of a given area, the daily iodine requirement would lie somewhere between 100 and 200 micrograms.[34]

The principle of thyroxine formation and decay was originally outlined by Plummer and Boothby [60] and subsequently developed by Thompson.[61] Plummer and Boothby observed that the daily rate of thyroxine decay ranged between 200 and 400 micrograms. Thus, a daily supply of thyroxine in this quantity maintained a normal basal metabolic rate in a totally myxedematous patient. Thompson and his group concluded that from 300 to 400 micrograms of thyroxine was necessary to maintain a normal basal metabolic rate in myxedematous patients at bed rest. On the basis of these results the amount of thyroxine supplied daily to the circulation by the thyroid gland, in order to maintain normal metabolic activity, is equivalent to from 130 to 260 micrograms of iodine. The uncertain factor here, however, is that iodine-containing end products of thyroxine decay may be retained and eventually reutilized by the thyroid gland in the further synthesis of thyroid hormone.

Studies of total iodine balance constitute the third principle which has been employed (figs. 1, 2 and 3). The iodine balance represents the daily amount of iodine lost or retained by the body, as ascertained by the difference between the amount of iodine intake and excretion. Pioneer determinations of iodine balance were accomplished by von Fellenberg, who reported low values and consequently a low daily requirement.[42c] The balance studies of Scheffer made in Pecs, Hungary, revealed that 54 micrograms of daily iodine intake was sufficient to maintain the iodine balance in a normal person.[62]

Ohio State University studies were made on normal persons maintained at bed rest on a monotonous diet low in iodine content, under controlled hospital conditions (figs. 1, 2 and 3). In these circumstances the basal human adult iodine requirement was found to range from 44 to 75 micrograms daily and to average 67 micrograms, or approximately 1 microgram per kilogram of body weight.[63] This average daily requirement is comparable to that determined by Scheffer. However, it should be emphasized that it applies to adults maintained under controlled basal conditions. Moreover, to arrive at an optimal iodine requirement, it is necessary to take into account individual activity as well as the varied stress and strain of existence.

After consideration of the difference in iodine intake between goitrogenous and nongoitrogenous regions and the amount of iodine estimated as necessary to maintain normal metabolic activity, 2 micrograms daily per kilogram .of body weight, together with the daily basal requirement of 1 microgram, can be reasonably justified as an amount sufficient to account for basal needs, those of ordinary activities and also some for reserve. The optimal daily requirement would thus be somewhere near 200 micrograms for an adult of 70 Kg., a value compatible with Elmer's deduction from various investigations that the human optimal requirement ranges between 100 and 200 micrograms daily.[15] The pregnant woman should receive additional iodine.[41a] A sufficient amount will be supplied by the use of iodized salt.[39]

Various methods of supplying supplemental iodine to the inhabitants of iodine-deficient areas have been advanced. These include the use of foods known to be rich in iodine, iodinization of water supplies, administration of iodine at regular intervals in the form of solutions or tablets, the general use of iodized salt and the consumption of iodized milk.

The use of iodized salt has thus far proved the most widely adopted method. The nearly universal employment of common salt for seasoning and cooking, as well as the ready preparation and low cost of iodized salt, makes this the popular method. The use of milk with an increased iodine content has also been suggested as suitable (fig. 1),[8b] especially for children who ordinarily consume large quantities. Effective iodine prophylaxis should conform to local conditions, since no single method will reach all those persons who need iodine.

The iodized salt originally recommended in 1924 by the Michigan State Medical Society in conjunction with the State Board of Health, and subsequently employed in Michigan with such outstanding results, originally contained 0.02 per cent of sodium iodide. However, after careful consideration, the Goiter Study Committee of the American Public Health Association reached the conclusion that the addition of 0.01 per cent of potassium iodide plus a stabilizer should be sufficient.[4] The importance of a stabilizer was emphasized in view of previous experience that iodine may be lost from iodized salt and thus impart a yellowness and a halogen odor on liberation of elemental iodine.

It has been estimated that the average adult ingests about 6.2 Gm. of salt daily. Calculated on this basis, the approximate amount of potassium iodide intake would be 620 micrograms, which is equivalent to about 474 micrograms of iodine. This is more than twice the amount we have suggested as optimal and would amply provide a person with a sufficient reserve.

## SUMMARY AND CONCLUSION

The universal prevention of endemic goiter and its sequelae will depend not only on the preparation and consumption of adequately iodized salt but also on the persistent education of all peoples to the necessity of its continued use. This is slowly but surely being accomplished. We may even look forward with sound hope to the eventual control of endemic goiter.

It cannot be too frequently repeated that iodine plays an indispensable role in the human organism and an indisputable role in medicine. Its prophylactic usage to insure the well-being of man and his essential domestic animals deserves continued emphasis. Thus, the element iodine is to the normal functioning thyroid gland as water to cultivated ground. Deprivation of this necessary substance, even to a slight degree, produces changes in the entire organism, harmful to the individual and significant to a people. A sufficient amount of iodine intake is a biologic necessity.

## THE MEDICAL SUPPORT FOR COMPULSORY SICKNESS INSURANCE.

In the editorial published in The Journal last week on the assessment and public opinion, attention was called to the fact that the medical profession as a whole gives but little support to Mr. Oscar R. Ewing's propaganda in behalf of compulsory sickness insurance. The same pressure groups that have been apparent in the past are again visible on the public horizon. Chief among them, because of its financial support, is the so-called Committee for the Nation's Health, Inc., headed by Dr. Channing Frothingham, motivated and controlled by Mr. Michael M. Davis, Ph.D., who likes to be called "doctor," and largely supported through Mr. and Mrs. A. D. Lasker and some of their friends. When the House of Delegates of the American Medical Association unanimously voted the $25 assessment to promote voluntary health insurance and to educate the American people regarding the ideals of American medicine and the dangers of a *politically controlled* compulsory sickness insurance system, Dr. Channing Frothingham of Boston voluntarily gave an interview to the press alleging that the doctors of the grass roots would never support the action of the House of Delegates. Enough response has already occurred to indicate that Dr. Channing Frothingham was without any exact knowledge on which to base that statement. Indeed, he is so far removed from the activities of the American Medical Association that his judgment could have but little basis. Dr. Frothingham must be pardoned, however, since he has apparently some difficulty in learning facts of even greater importance. Here is the testimony which he gave in hearings before the Senate Committee on Education and Labor:

> Senator Donnell: Doctor, this is not any aspersion on you, but I want to get at just who those that really organized this Committee for the Nation's Health are.
>
> Who did that?
>
> Dr. Frothingham: I do not know. That is a tough one.
>
> Senator Donnell: Who was the first man you ever heard about it from? That is fine grammar I used here. But, from *whom did you first hear about the organization of this* committee?
>
> Dr. Frothingham: Darned if I know. I would have to look that up in my files.
>
> Senator Donnell: Was it not Dr. Michael M. Davis?
>
> Dr. Frothingham: It might well have been. I can imagine of no better organizer.
>
> Senator Donnell: I expect you are right. He is a pretty good organizer.
>
> The Chairman [Senator James E. Murray]: Doctor, I might ask you a few questions there.
>
> *Is it not a fact that you and other physicians like you* have been interested in improving medical care in this country and have been coming to Washington here and attending previous hearings that we have had on this problem, and have been contacting and talking to people like myself, who have been interested in this problem for some time?
>
> I have known you myself personally for several years, prior to the organization of this committee, and I have known of your interest in this problem.
>
> Dr. Frothingham: Yes.
>
> The Chairman: You have discussed it with me many times, and I have seen you at meetings where the matter is *being discussed. The organization of this committee is an* evolution.
>
> Dr. Frothingham: That is right.
>
> The Chairman: Which has been taking place in this country for a period of years.
>
> Dr. Frothingham: That is perfectly true. It must be at least three years that we have been mulling over this subject.
>
> The Chairman: Yes.
>
> Senator Donnell: And Doctor, your mulling culminated on the 23d of Februrary of this year in the incorporation of this committee, is that right?
>
> Dr. Frothingham: The mulling brought out this particular group in favor of it. There are other groups working on it.
>
> Senator Donnell: Is Dr. John P. Peters also in this Committee for the Nation's Health?
>
> Dr. Frothingham: *I have got to look at that, too.*
>
> Yes; he is only a couple of lines lower down than Butler.
>
> Senator Donnell: Doctor, I will not ask you in detail on this, but without reference to your leaflet or your files, do you know anybody that is on this committee except yourself and Mr. Michael Davis?
>
> Dr. Frothingham: Yes.
>
> Senator Donnell: Who?
>
> Dr. Frothingham: Well, now, let me think.
>
> I went to a meeting, or a couple of meetings in New York. There was a man by the name of Rothchild and a lady by the name of—she had a wonderful suite of rooms. I cannot remember what her name was.
>
> The Chairman: Where did this meeting take place, Doctor?
>
> Dr. Frothingham: Once in a house and once in the suite of rooms. We went to two meetings. I really cannot remember her name.
>
> The Chairman: You may use the pamphlet and refresh your memory if you desire. That is a practice in the legal profession.

Senator Donnell: That is all right. I would really like for him to tell us if he has any memory about anybody there except Mr. Rothchild and this lady.

Dr. Frothingham: Yes. Dr. Davis, the nonmedical Dr. Davis.

Senator Donnell: Dr. Michael Davis, also?

Dr. Frothingham: Dr Michael M. Davis.

Senator Donnell: This is an organization meeting?

Dr. Frothingham: No; this is the executive committee, this is after the movement was over and the child was born.

Senator Donnell: All right.

Dr. Frothingham: I cannot remember her name to save my soul. It is lucky I am getting too old to practice, is it not?

And then a lady by the name of Norman. She was not the one that owned the villa.

Senator Donnell: You cannot remember the name of the lady who had the villa?

Dr. Frothingham: I will tell you, Dr. Davis can tell you that.

Senator Donnell: Dr. Michael Davis?

Dr. Frothingham: He is my memory man.

Senator Donnell: All right.

Additional support for compulsory sickness insurance comes from a committee known as the Committee of Physicians, which began a good many years ago with some four hundred names and which now has apparently dwindled to thirty-five. Several of the thirty-five are also officers of the Committee for the Nation's Health, Inc.; a few are names notable in medicine for contributions to medical advancement. A good many are full time salaried teachers. Under the leadership of Dr. John Peters of Yale University School of Medicine, who seems to represent 95 per cent of the working force of this group, they discuss with a vast amount of wordage and with a great deal of seesaw motion every step in the consideration of the problem. Apparently they have a mailing list of some thousands of names, but the source of their financial support is not apparent.

Third in the opposition is the Physicians Forum headed by Dr. Ernst Boas of New York. This agency may muster as many as 3,000 members, almost wholly concentrated in Philadelphia, New York and Washington. Recently the president of the New York County Medical Society, Dr. William B. Rawls, accused Dr. Boas of membership in a great many leftist organizations. An attempt is now being made to cause Dr. Rawls to retract his statement, and the matter is before the comitia minora of the New York County Medical Society.

This apparently represents the organized medical opposition to the policies of the American Medical Association. Certainly the opposition is pitiful in its proportions compared to the vast support of the American Medical Association's policies given by an exceedingly preponderant majority of the latter's more than 135,000 members.

---

## THE WORLD HEALTH ASSEMBLY

The first World Health Assembly met in Geneva from June 24 to July 24, 1948. Already many of its activities have been noted in the news columns of The Journal. The organization is complex, with special committees devoted to a variety of interests. At present the chief concerns are malaria, tuberculosis, venereal disease and maternal and child health. Programs have been established for these four fields which will be begun in 1949 and developed over succeeding years. The Assembly estimates that more than one fifth of all deaths throughout the world from all diseases arise from environmental conditions controllable by sanitary engineering. An expert committee is to be established for this field also. As soon as measures for the improvement of environmental hygiene can be taken by governmental action without recourse to such technics as education, instruction or individual treatment, the World Health Organization looks for prompt results in improving sanitary conditions throughout the world.

Nutrition is the environmental factor which is agreed to have the greatest bearing on health. Obviously, therefore, the World Health Organization will soon have established a special committee on this subject to be concerned particularly with endemic goiter and pellagra.

Geneva is the permanent headquarters of the World Health Organization. Arrangements have been made for suitable relationships with UNESCO, United Nations and similar groups. The budget for 1949 is $5,000,000; of this amount $1,000,000 has been assigned to the six subjects mentioned on the priority list. Another sum of $700,000 has been set aside for fellowships, medical literature and teaching material, and additional appropriations have been made for international epidemiologic studies, editorial and reference services, public health administrations and health statistics.

A World Health Day is to be held in the future each year on July 22, the date on which the constitution of the World Health Organization was signed by sixty-one states. The next Health Assembly is to be held in Europe. The representation from the United States is considerable and includes, among others, Dr. James R. Miller, who is a trustee of the American Medical Association. The active representative is Dr. H. van Zile Hyde.

# Current Comment

## PROPORTION OF PHYSICIANS TO POPULATION

In a broadcast over the Mutual Chain entitled "Meet the Press" early in December, Mr. Oscar R. Ewing, Administrator of the Federal Security Agency, was asked the simple question, "Do you know of any country that has more doctors in proportion to its population than the United States?" To this Mr. Ewing replied, "I don't. . . . I just don't know the answer one way or the other. Whether there are or aren't. I can't tell you." For the information of Mr. Ewing and of others who may have doubts that the United States has more doctors in proportion to population than any other country in the world, The Journal presents a recent table based on a survey conducted in 1948 by the World Medical Association. In this table the number of doctors per 100,000 population is listed, and in the right hand column the number of people per doctor. It should be obvious that except for Palestine (Jewish), where there are great numbers of refugee physicians from Central Europe, the United States is well ahead of the rest of the world in proportion of physicians to population.

*Total Population, Physicians and Physicians per 100,000 Population and Population per Physician in a Representative Group of Countries**

| Country | Population | Doctors | Doctors per 100,000 Population | Population per Doctor |
|---|---|---|---|---|
| United States | 141,228,673 | 197,605 | 140 | 710 |
| Great Britain | 48,788,000 | 55,771 | 114 | 870 |
| Iceland | 132,000 | 149 | 113 | 890 |
| Denmark | 4,014,725 | 4,250 | 105 | 950 |
| Canada | 11,489,713 | 11,901 | 104 | 970 |
| New Zealand | 1,750,000 | 1,800 | 103 | 970 |
| Australia | 7,500,000 | 7,137 | 95 | 1,100 |
| Switzerland | 4,000,000 | 3,806 | 95 | 1,100 |
| Sweden | 6,700,000 | 6,360 | 95 | 1,100 |
| Spain | 27,000,000 | 25,142 | 93 | 1,100 |
| Norway | 3,126,000 | 2,900 | 93 | 1,100 |
| Netherlands | 9,000,000 | 8,000 | 89 | 1,100 |
| Luxemburg | 281,572 | 234 | 83 | 1,200 |
| Czechoslovakia | 12,000,000 | 9,300 | 78 | 1,300 |
| France | 40,000,000 | 30,000 | 75 | 1,300 |
| Eire | 3,000,000 | 2,000 | 67 | 1,500 |
| Bulgaria | 7,022,206 | 4,563 | 65 | 1,500 |
| Finland | 3,865,000 | 1,737 | 45 | 2,200 |
| Union South Africa | 11,391,949 | 4,800 | 42 | 2,400 |
| Egypt | 17,000,000 | 4,000 | 24 | 4,200 |
| Palestine (Arab) | 1,300,000 | 291 | 22 | 4,500 |
| China | 450,000,000 | 20,000 | 4 | 25,000 |
| Palestine (Jewish)† | 625,000 | 2,386 | 382 | 260 |

* Source: Draft Report on the Medical Professions in 23 Countries, New York, World Medical Association, 1948, table 1. The only other current figure available is 16,930 physicians in Brazil in 1946, which has a population of about 45,000,000, giving 36 physicians per 100,000 population (J. A. M. A. **138**: 527 [Oct. 16] 1948). This is greatly out of line with the estimate for 1933, which placed Brazil's ratio as equal to Sweden's.

† "The high rate of 3,818 [per million] for the Jewish section of Palestine is probably attributable to special temporary circumstances."

## THE AGES OF PHYSICIANS IN 1940 AND IN 1948

Elsewhere in this issue is a tabulation prepared by the Bureau of Medical Economic Research of the American Medical Association of the ages of all physicians in the United States, including those who are not in active practice. Contrary to the claims made by some advocates of compulsory sickness insurance, the average age of physicians has declined slightly since 1940. The percentage who are under 50 years of age has increased from 57.5 in 1940 to 60.2 in 1948. The percentage at age 70 and over has also increased. The decline in the median age from 45.8 years to 44.4 reflects the results of the speed-up program of medical education during World War II. This article is the second in a series. The first article appeared in The Journal of Aug. 21, 1948 and revealed that the number of physicians has increased 14 per cent since 1940, while the total United States population has increased only 12 per cent. Subsequent tabulations will be reported in The Journal by the Bureau of Medical Economic Research from time to time as its new punch card system nears completion.

## INSTITUTE OF INTER-AMERICAN AFFAIRS

Recent reports of the Institute of Inter-American Affairs indicate that a realistic inventory and appraisal of programs which the Institute has been conducting in the countries of the Western Hemisphere since 1941 is now under way. The primary purpose of reappraisal at this time is the establishment of definite recommendations toward provisions for the future of the entire program. Since 1941, first under the auspices of the Coordinator of Inter-American Affairs and subsequently under the direct control of the State Department, the Institute has been engaged in three-pronged actively cooperative programs in health, education and agriculture with some twenty of the Western Hemisphere republics. The Institute program has received less than deserved publicity and recognition in the United States, primarily because of overshadowing news events connected with the war and with subsequent postwar activities in the European and Asiatic areas. However, the work of the Division of Health and Sanitation of the Institute alone has been the greatest operating international public health effort both in scope and area covered ever undertaken by a single public health agency. The health projects, although they vary to some extent in all countries, are directed toward public health education, improvement of basic sanitary facilities, hospital construction and operation, special disease campaigns and training of personnel. The selective approach of the Institute to problems of agriculture, health and education is based principally on the belief that hunger, disease and ignorance are the outstanding allies of totalitarianism in the present world situation. The program of the Institute represents the spirit of good neighborliness characteristic of international relations among the countries of the Western Hemisphere for many years past. Such a program of proved effectiveness in friendly countries of the Western Hemisphere deserves continued national support.

# ORGANIZATION SECTION

## Washington Letter

*(From a Special Correspondent)*

Dec. 27, 1948.

### Radical Changes Advocated by Hoover Commission Unit

The Commission on Organization of the Executive Branch of the Government—better known as the Hoover Commission—will make several controversial recommendations to Congress in January if it indorses the views of its "task force" committee that studied the National Military Establishment. These recommendations affect not only the Army, Navy and Air Force medical departments but bear directly on Veterans Administration and U. S. Public Health Service as well. In addition, their adoption would exercise marked influence on nongovernmental medical care and hospitalization, with particular reference to those proposals for a system of "federal health insurance," amendment of the Selective Service Act to legalize drafting of A. S. T. P. and V-12 graduates who saw little or no active service in the military medical corps and unification of federal hospitalization.

Following are some of the recommendations of the Eberstadt committee, which surveyed the National Security Organization for the Hoover Commission, together with observations culled from its detailed report:

Establish a single federal hospital system, which would administer all government hospitals—Army, Navy and Veterans Administration included—located within the continental limits.

"The proposed Federal hospital system could well develop one of the strongest graduate training programs in American medicine, with the highest professional standards of medical service. At the same time it could guarantee a reservoir of skilled personnel who would be attracted to government service through appreciation of the rewards in such a service and the possibilities of a distinguished career in medicine."

Study the feasibility of reducing the patient load of military hospitals by curtailment of services to dependents, the point being noted that 42 per cent of all beds in naval hospitals are occupied by nonservice patients.

"Withdrawal of these privileges within the services might raise serious morale problems. The logical solution to this problem may be the same as in civilian life and industry, namely, provision of hospital and medical insurance to cover the needs of such dependents. It would, obviously, be necessary to increase monetary allowances to provide for such an insurance plan, but such provision would probably be more economical in the long run. Such insurance coverage could be used either in Federal or civilian institutions. Medical service for dependents in outlying posts or overseas stations would, of course, continue."

Let the armed forces strive for greater conservation of their medical man power and enhancement of its efficiency.

"In the committee's opinion, service estimates of their medical and dental needs are excessive and are much higher in proportion to numbers of personnel than in civilian life. The utilization of doctors in administrative rather than in medical positions, maldistribution of medical personnel, wasteful medical practices and the diversion of service medical efforts to care for a great patient load of service dependents, veterans and various Federal employees contributes to the apparent service shortage. There is, however, a great national shortage of doctors—particularly of specialists—and even the correction of service medical deficiencies will not solve this problem."

The Eberstadt committee urges establishment of a separate medical department to serve the U. S. Air Force, criticizes the recent Army order (Circular No. 342, Nov. 1, 1948) which subordinates the Surgeon General to the Director of Logistics, suggests that the medical division of National Security Resources Board coordinate the allocation of affiliated reserve medical units for duty in event of emergency and praises the record of the Office of Naval Research for its work in initiating and supervising medical and other types of scientific studies.

"It should be emphasized," says the report, "that the proposal for the establishment of a federal hospital system does not involve 'socialized medicine'; such a consideration is entirely beyond the committee's purview."

Through the services of Drs. Howard A. Rusk and Richard D. Meiling, the Eberstadt committee had close liaison with the Voorhees committee, another Hoover Commission "task force" whose job consisted of surveying the federal government's activities in the health, medical and hospital fields as a whole. Findings of the latter group were scheduled to be made public in late December. The Eberstadt report indicated that both committees had found agreement on establishment of a unified federal hospital system and the wisdom of studying institution of "a system of federal health insurance for service personnel and dependents."

### Forrestal's Medical Advisors to Meet in January

Although a definite date for the new group's first meeting had not yet been fixed a week before Christmas, indications were that the Armed Forces Medical Advisory Committee would be assembled in mid-January. Appointment of such a group was one of the recommendations of the Eberstadt committee. It proposed, however, that the chairman be a physician. Secretary of Defense Forrestal's designee is a layman, Charles Proctor Cooper, president of the board of trustees of Presbyterian Hospital (New York) and formerly vice president of American Telephone & Telegraph Company. Three of the advisory committee members—Drs. Michael DeBakey, Paul R. Hawley and Edward D. Churchill—served on the Hoover Commission's "task force" that investigated federal activities in medical care and hospitalization. Another, Dr. Raymond B. Allen, president of the University of Washington, was a member of the Eberstadt committee, while Drs. Rusk and Meiling were liaison officers. The other civilians on the advisory group are Drs. Maurice C. Pincoffs, Paul Titus and Walter H. Scherer, the last named being a former president of the American Dental Association.

### Dr. Topping Promoted to Assistant Surgeon General

Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, has announced promotion of Dr. Norman H. Topping to Assistant Surgeon General. The rank is equivalent to that of brigadier general. Dr. Topping will continue in his present assignment as associate director of National Institutes of Health, research arm of the Public Health Service. Born in Missouri in 1908, Dr. Topping received his undergraduate and medical education at University of Southern California and was commissioned in the Public Health Service in 1936.

## Coming Medical Meetings

Annual Congress on Industrial Health, Chicago, Drake Hotel, Jan. 18-19. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 7-8. Dr. Donald G. Anderson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 4-5. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

American Society for Surgery of the Hand, Chicago, Jan. 21-22. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

International Post-Graduate Medical Assembly of Southwest Texas, San Antonio, Jan. 25-27. Dr. John J. Hinchey, P. O. Box 2445, San Antonio, Secretary.

Southeastern Allergy Association, Durham, N. C., Washington-Duke Hotel, Jan. 22-23. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia, S. C., Secretary.

Southeastern Surgical Congress, Biloxi, Miss., Jan. 24-27. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Ga., Secretary.

Western Section American Urological Association, Coronado, Calif., Hotel del Coronado, Jan. 17-19. Dr. Adolph A. Kutzmann, 1930 Wilshire Blvd., Los Angeles 5, Secretary.

# GOVERNMENT SERVICES

## ARMY

### TRAINING COURSES AVAILABLE IN CIVILIAN INSTITUTIONS

Training courses ranging in length from five months to a year to be given in specified civilian institutions during the fiscal year 1950 are now being offered to qualified Regular Army personnel, the Surgeon General has announced, as a development of the Medical Department's Career Guidance Plan evolved two years ago. The subjects include most of the medical and allied science fields at leading universities, colleges, hospitals and foundations. The Surgeon General's Office intends to train personnel whose records and aptitudes show them best qualified to draw the maximum benefits from advanced study. The program, tentatively established in twenty-five civilian institutions, has a twofold aim: to insure advancement in their respective specialties to each of the officers selected and to integrate the best of civilian medicine with military medicine. Information for applicants is set forth in SGO circular 134 dated Nov. 16, 1948. Applications for training are to be forwarded to the Surgeon General's Office prior to Feb. 1, 1949.

### NEW COMMANDANT OF MEDICAL CENTER

The Surgeon General announced December 9 the assignment of Brigadier General Paul H. Streit to command the Army Medical Center in Washington, D. C., succeeding Major General George C. Beach Jr., who died Nov. 18, 1948. General Streit was recently in command of Brooke General Hospital at Fort Sam Houston, Texas. He was graduated by the University of Texas Medical School and interned at John Sealy Hospital in Galveston, Texas, then joined the Regular Army Medical Corps and went overseas with the 87th Division in 1917. He did postgraduate nose and throat work at the University of Bordeaux and in 1919 joined the American Typhus Relief Expedition with headquarters in Warsaw, Poland. Among other assignments, he has been chief of the eye, ear, nose and throat service at Jefferson Barracks, Mo.; at Sternberg General Hospital in Manila; at Fort Leavenworth (Kansas) General Hospital; at the Army-Navy General Hospital, Hot Springs, Ark., and at the Letterman General Hospital, San Francisco. During the recent war he was chief surgeon of the Central Pacific Base Command and commandant of the Dibble General Hospital, the Army's center at Menlo Park, Calif., for treatment of blindness and for plastic surgery.

### MONTHLY MEDICAL MEETING

Dr. Owen H. Wangensteen, chief, department of surgery, University of Minnesota, Minneapolis, will address the Surgeon General's monthly medical meeting at Walter Reed Hospital January 24 on "The Etiology and Surgical Management of Peptic Ulcers." Major Edwin J. Pulaski, Surgical Research Laboratory, Brooke Army Medical Center, Fort Sam Houston, Texas, will speak on "The Control of Peritoneal Infection in Gastro-Intestinal Tract Surgery."

### INSTITUTE OF PATHOLOGY

The following doctors were at the Army Institute of Pathology, Washington, D. C., on the dates indicated, to act as consultants to the staff: Dr. Henry M. Goldman, Boston, November 4-5, and Dr. Herman Becks, George Williams Hooper Foundation, University of California, November 10-14.

### LETTERMAN HOSPITAL CELEBRATES FIFTIETH ANNIVERSARY

Letterman General Hospital, Presidio of San Francisco, celebrated its fiftieth anniversary on Nov. 23, 1948. The Surgeon General of the Army made the chief address. Brigadier General Frank L. Cole, hospital commander, directed the anniversary program. This hospital was designated a general hospital by the Secretary of War on Dec. 1, 1898, and thirteen years later was named in honor of Major Jonathan Letterman, a Civil War surgeon who devoted the last eight years of his life following retirement from the Army to community service in the Presidio of San Francisco. Major Letterman was the son of an eminent Pennsylvania physician. He received his M.D. degree from Jefferson Medical College in 1849 and joined the Army as an assistant surgeon in that year. He served in at least three Indian campaigns. On July 4, 1862, he reported for duty as Medical Director of the Army of the Potomac. The outbreak of hostilities between the states found the Surgeon General almost totally unprepared. When Letterman took over as medical director, he found neither plans, personnel nor equipment for collecting the wounded from the battlefields, for transporting them to the rear or for caring for them in hospitals. Letterman immediately set up an efficient evacuation operation, organized an ambulance corps, devised an effective supply plan and inaugurated a field hospital system which was the forerunner of the current station hospital. These were all innovations. While similar proposals had been made before at various times, all were either ignored or discarded. Letterman's entire program, which received its first trial at Fredericksburg in 1862, was later enacted into law with a few minor changes. Thus was established the basic model of the current field organization of the Army Medical Department.

# NAVY

## SPECIAL WEAPONS PROJECT

Regular and Reserve officers of the Navy are invited to attend an indoctrination course on the medical aspects of atomic explosion at the Sternberg Auditorium, Army Medical Center, Washington, D. C., Jan. 24 to Feb. 1, 1949. Any regular or reserve officer desiring to attend this course should apply by air mail letter to the Bureau of Medicine and Surgery not later than January 10. Accepted candidates will be requested to attend this course at their own expense under TAD authorization orders with government air transportation if available.

## FIRST ACTIVE DUTY

The following lieutenants (jg) in the medical reserve corps have received orders to their first active duty as interns at the Naval hospitals indicated: Konstantin H. Geocaris of Chicago, to Oakland, Calif.; James A. Hardie of Columbus, Ohio, to Oakland, Calif.; Harold P. Hargreaves of Salt Lake City, to St. Albans, L. I., N. Y.; Raymond J. Krause of Columbus, Ohio, to San Diego, Calif., and William C. Love of Columbus, Ohio, to Long Beach, Calif.

## POSTGRADUATE INSTRUCTION

The following medical officers have been nominated to the courses in postgraduate instruction indicated: Comdr. John C. Dunn, Brooklyn, to a fellowship in children's orthopedics at the James W. Riley Memorial Hospital, Indianapolis; Lieut. George C. Beattie, Bowling Green, Ohio, to a fellowship in children's orthopedics at the Children's Hospital, Boston, and Lieut. (jg) Lyle H. Prenzler, Bloomington, Ill., to a residency in psychiatry at St. Elizabeth's Hospital, Washington, D. C.

## INSTRUCTION IN CIVILIAN INSTITUTIONS

The following reserve medical officers have been ordered to their first active duty and will receive postgraduate instruction under the Navy's Medical Training Program in civilian institutions: Lieutenants (jg) Robert P. Dobbie Jr., Buffalo, N. Y., to a residency in general surgery at University Hospital, Ann Arbor, Mich.; Paul D. Doolan, Hamden, Conn., to a residency in internal medicine at Boston City Hospital, Boston; James L. Keating, Falls Church, Va., to a residency in general surgery at Georgetown University Hospital, Washington, D. C., and John W. Troy, Washington, D. C., to a residency in general surgery at Georgetown University Hospital, Washington, D. C.

## PERSONALS

Comdr. T. A. Harris, M.C., chief of the Division of Psychiatry of the Bureau of Medicine and Surgery, has been appointed a member of the American Board of Psychiatry and Neurology.

Lieut. (jg) Frank D. Fuller has transferred from active reserve status to the Regular Navy Medical Corps.

Lieutenants (jg) William C. Curtis of Milwaukee and Navon M. Olson of Lake Mills, Iowa, reserve medical officers, have been ordered to their first active duty.

## GUEST LECTURER AT MEDICAL CENTER

Dr. Arthur W. Allen of Boston addressed the meeting of the Naval medical officers at Bethesda, Md., Dec. 17, 1948, on "Gastric and Duodenal Ulcers." This was the fourth lecture of the monthly series by guest speakers sponsored by the Medical Center.

# VETERANS ADMINISTRATION

## NEW METHOD OF STAFFING A HOSPITAL

The Veterans Administration announces that a new method of staffing will be in effect when the Veterans Administration hospital at Grand Junction, Colo., opens in January 1949. The new 150 bed general medical and surgical hospital, located about half way between Salt Lake City and Denver, will not have any residents. Instead, it will be staffed with men who have completed their formal residency training and are prepared to put in two years of practice in their specialty under supervision of certified specialists. This training is necessary as part of the requisite for becoming certified specialists. The Veterans Administration said that the program—under the supervision of Dr. Richard Young and Dr. Ward Darley, deans of the medical schools of Utah and Colorado universities, respectively—will result in a continually rotated staff of high caliber.

## INTENSIVE TREATMENT OF MENTAL PATIENTS

During the last year an intensive treatment program, officially identified as the Reintegrative Research Program, has been in effect at the Veterans Hospital at Northport, Long Island, in an attempt to rehabilitate patients with the more serious types of mental disease. This program, the Veterans Administration announced Dec. 10, 1948, is beginning to have results. Two hundred World War II veterans whose mental illnesses had failed to respond to previous methods of treatment were selected to take part in the program. These patients now are on a completely supervised schedule from 7 a.m. to 9 p.m. five days a week. The basic aim is to increase the patients' interest, starting with some simple form of athletics, to relieve the aggressive tendencies and tensions which many of them display. The group is alternated between occupational therapy, corrective therapy, athletics and recreation. Miniature bowling and table tennis, for example, are suggested to encourage the spirit of competition. Individual and group psychotherapy is available. As individual patients show interest in the activities, they are advanced to more difficult tasks. While progress is extremely slow, it indicates a potential discharge rate of nearly 40 per cent for a class of patients previously considered probably lifetime hospital patients. In the group mentioned, 16 patients have returned home and 14 others will soon leave on trial visits. Forty-five others are considered good prospects for eventual release; 2 of the 16 discharged patients are now employed full time.

The program at Northport has been under the direction of Dr. William L. Harris, with Dr. Louis F. Verdel, hospital manager, as coordinator. Since its inauguration at Northport in December 1947, the program has been adopted by several other Veterans Administration neuropsychiatric hospitals.

## RESIDENCIES IN NEUROLOGY

An additional residency training program for physicians desiring to train in neurology under the Veterans Administration has been organized by the Philadelphia Deans Committee. This residency covers a period of three years or less, depending on the previous experience of an applicant, and is designed to prepare residents for certification in neurology by the American Board of Psychiatry and Neurology. The program includes rotation through the Veterans Administration Hospital, Coatesville, Pa., Veterans Administration Regional Office, Philadelphia, and the Philadelphia General Hospital. Applications should be sent to the Manager, Veterans Administration Hospital, Coatesville, Pa.

## NEW HOSPITAL AT HOUSTON, TEXAS

Bids for the construction of a thousand bed veterans neuropsychiatric hospital at Houston, Texas, have been awarded to the low bidders for $17,788,000 for general construction and $529,000 for staff quarters; also to another corporation $470,380 for installation of elevators and $95,100 to still another corporation for the construction of a water tank.

### THE NUMBER OF VETERANS

The Veterans Administration announced that as of October 31 the total number of living veterans of all wars was 18,819,000, of whom 14,997,000 were veterans of World War II. The total number of veterans in hospitals on that date was 105,762, of whom 68,992 were veterans with non-service-connected disabilities. There were in addition 15,026 veterans beneficiaries in Veterans Administration homes. Two new Veterans Administration hospitals had been completed through the end of the month of October, and eighty-nine veteran hospitals were in various stages of the construction program.

### PERSONAL

Dr. A. Ray Dawson has resigned as assistant medical director for physical medicine rehabilitation in the Veterans Administration and will return to Richmond, Va., as chief of physical medicine at the McGuire Veterans Administration Hospital. His successor will be Dr. A. B. C. Knudson.

Dr. Joseph M. Farrell has been appointed to the full time staff of the Veterans Administration hospital, Huntington, W. Va. Dr. Farrell was graduated from Long Island College of Medicine in 1942 and served in the Army Medical Corps during the recent war.

## PUBLIC HEALTH SERVICE

### NATIONAL ADVISORY HEART COUNCIL

At a recent meeting in Bethesda, Md., this council resolved that about $30,000,000 would be necessary for adequate execution of the plan to assist hospitals and medical schools with the necessary laboratory facilities for research on heart disease on a five year basis. Applications were received from fifty-one hospitals and medical schools, but further study of them was decided on before final recommendation to the Surgeon General. The council also recommended, subject to its further review, applications totaling about $3,000,000 for promising research investigations. Applications were considered from thirty-seven medical schools for grants to improve and expand cardiovascular teaching and approval was tentatively recommended of applications totaling about $1,350,000; also considered were applications for grants for control projects (special pilot studies) preliminary to the development of statewide and community heart disease control programs throughout the country. The council recommended the approval of applications for about $200,000 for these special studies, for which funds are presently available. The next meeting of the National Advisory Heart Council, which is composed of leaders in medical science and public affairs with Dr. Paul D. White of Boston as director, will be held in New Orleans February 27 to March 1, 1949.

### REGULAR CORPS EXAMINATION FOR NURSE OFFICERS

A competitive examination for appointment of nurse officers in the regular corps of the U. S. Public Health Service will be held on March 17, 1949, at various points in the United States. Appointments are permanent in nature and provide opportunities for a lifetime career in the fields of clinical and public health nursing at Marine hospitals and in a variety of public health programs. Appointments will be made in the grades of junior assistant, assistant and senior assistant nurse officer. Annual entrance pay is from $2,955.50 to $4,489, as determined by the grade of appointment and existence of dependents. All applicants must be registered nurses with a baccalaureate degree from an approved school of nursing. Past nursing experience in the Army, Navy or Public Health Service may serve, in certain instances, in lieu of academic degree. Additional information may be obtained by writing to the Surgeon General, United States Public Health Service, Washington 25, D. C., Attention: Division of Commissioned Officers.

### MENTAL HEALTH COUNCIL

The meeting of The National Advisory Mental Health Council in Washington, D. C., December 12-13, marked the completion of two and one-half years of the expanded national mental health program authorized by the National Mental Health Act of 1946. The council recommended twelve new mental health research grants which totaled $121,735 and undergraduate training grants in psychiatry in forty-two schools of medicine, approximating $1,500,000 over a three year period. The applications now go to the Surgeon General of the Public Health Service for official approval and payments will be made as funds become available. As the entire appropriation for research and training for the current fiscal year—a total of $2,000,000—has been previously obligated, payments on the grants approved at this meeting will not be made before the 1950 fiscal year. The National Advisory Mental Health Council is composed of authorities in mental health appointed to advise the Public Health Service in its administration of the Mental Health Act.

### HOSPITAL SURVEY AND CONSTRUCTION ACT

The Hospital Facilities Division of the Public Health Service announced that as of Nov. 26, 1948, five hundred and sixty-four initial project applications for federal grants under the Hospital Survey and Construction Act had been approved by the Surgeon General. The Division estimated that over one hundred projects are actually in the construction stage. The total estimated cost of the five hundred and sixty-four projects is over $341,000,000. The federal share of this is estimated at over $103,000,000.

### PERSONAL

Dr. Maurice A. Roe has been appointed medical director for the Public Health Service in Region 8 of the Federal Security Agency with headquarters in Dallas, Texas, succeeding Dr. Knox E. Miller, who has been assigned to the City Health Department in Milwaukee.

Dr. Warfield Garson, formerly visiting associate research specialist at the New Jersey Agricultural Experiment Station, Rutgers University, New Brunswick, has been placed in charge of antibiotic research at the V. D. Research Laboratory, U. S. Marine Hospital, Staten Island, N. Y.

## MISCELLANEOUS

### DR. HUMPHREYS HEADS RADIOMETRY RESEARCH

Curtis J. Humphreys, Ph.D., has been named chief of the Radiometry Section of the Atomic and Molecular Physics Division, National Bureau of Standards, where he will be concerned with standards of radiant energy, analysis of infra-red and ultraviolet absorption and emission spectrums, line emission spectrums and flame spectrums in the infra-red, and the utilization of photoconducting detectors in high resolution spectroscopy.

Dr. Humphreys, who is well known for his research in spectroscopy, has been associated with the Bureau since 1928, with the exception of 1934 and 1935, when he was on the staffs of the Massachusetts Institute of Technology and the United States Coast and Geodetic Survey. From 1922 to 1927 he was a member of the faculty of Western Reserve University and from 1921 to 1922 was a research assistant at the University of Michigan. Between 1919 and 1921 he was an instructor in physics at the University of Kentucky. He received his Ph.D. from the University of Michigan in 1928.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ARIZONA

**Reorganize State Department of Health.**—The new plan for organization adopted by the State Board of Health for the Arizona State Department of Health establishes the following bureaus in the department: administration, preventive medical services, local health services and sanitation. Dr. Elmore P. Kalbaugh, recently assigned to Arizona by the U. S. Public Health Service, has assumed the position of director of the state health department's Division of Tuberculosis Control. He is a graduate of the Medical College of Virginia at Richmond.

## CALIFORNIA

**Third Institute on Alcohol Studies.**—A third Institute on Alcohol Studies is tentatively set for the first week in February to be held on the Los Angeles campus of the University of California under the auspices of the Department of Institutes of University Extension. Representatives of social, medical, education, religious and legal groups will be asked to present their views in large general sessions, and opportunity for critical discussion will be provided in small sessions. Persons interested in attending may obtain information from the Department of Institutes, University of California, Los Angeles 24.

## CONNECTICUT

**Yale Retirements.**—The retirement of three members of the faculty of Yale University School of Medicine has been announced: Dr. Arthur H. Morse, professor of obstetrics and gynecology; Dr. George M. Smith, research associate in anatomy with the rank of professor, and Miss Alice M. Hunt, assistant professor of anesthesia.

**Dr. Fisher Honored.**—The new laboratory of the Middlesex Hospital in Middletown is to be named in honor of Dr. Jessie W. Fisher "to mark her long and faithful service to the institution as pathologist and bacteriologist." After graduation from the Woman's Medical College, Philadelphia, in 1893, Dr. Fisher went to Middletown as a pathologist in the Connecticut State Hospital, and formed her connection with the Middlesex Hospital in 1916.

## DISTRICT OF COLUMBIA

**Seminar on Tumors of the Skin.**—The Washington Society of Pathologists of Washington, D. C., announces a joint Baltimore-Washington Seminar on Tumors of the Skin to be held in the auditorium of the Medical Society, District of Columbia, February 5, from 10:30 a. m. to 4:30 p. m. Col. James E. Ash, Washington, and Drs. Arthur A. Allen, Paterson, N. J., and Elson B. Helwig, St. Louis, will serve as principal discussants. Pathologists, dermatologists and other physicians in Washington and surrounding areas are cordially invited. Study material for the seminar will be issued from the agency of the American Registry of Pathology on or about December 27 for one month's study prior to the day of the seminar. Washington and Baltimore members of the respective pathology societies are requested to return the diagnostic list on the study material to Dr. Ruell A. Sloan, Curator of the Army Medical Museum, no later than January 23.

## GEORGIA

**Obstetric Seminar.**—An Obstetric Seminar for general practitioners was held at the University of Georgia School of Medicine, Augusta, Dec. 6-10, 1948, under the auspices of the departments of public health of Georgia and South Carolina and under the direction of Drs. Guy V. Rice, Albany, and Hilla Sheriff, Columbia, S. C. About fifty attended.

**Personal.**—Dr. Jack C. Norris, Atlanta, has been named chairman of the cancer commission of the Medical Association of Georgia, succeeding the late Dr. James L. Campbell, Atlanta. The commission coordinates the cancer control program of the state medical association, the American Cancer Society and the Cancer Control Division of the Georgia Department of Public Health.

## ILLINOIS

**Personal.**—Dr. James R. Hughes of Oak Park has been appointed chief of medical service at the Veterans Hospital in North Little Rock, Ark., and also has accepted an apointment as associate professor of medicine at the University of Arkansas School of Medicine, Little Rock. Dr. Hughes formerly was an associate to an attending physician of Cook County Hospital.

**Dr. Sayago to Address Joint Meeting.**—Dr. Gumersindo Sayago of Cordoba, Argentina, will be the after dinner speaker at a joint meeting of the Chicago Tuberculosis Society and the Illinois Chapter of the American College of Chest Physicians at the Congress Hotel, Chicago, January 7 at 6:30 p. m. Dr. Sayago has just returned from a medical mission to the Philippine Islands, which was sponsored by the World Health Organization. Reservations should be made immediately with Dr. Edwin R. Levine, secretary of the Chicago Tuberculosis Society, 500 North Dearborn Street, Chicago 10. A scientific program will be presented after the meeting.

**Television Enlisted for Health Education.**—New technics in health education made possible by television are being worked out in a series of radio programs recently begun by WGN-TV, Chicago, with the cooperation of the Educational Committee of the Illinois State Medical Society. The first program featured a 9 year old boy, a diabetic, demonstrating how he gives himself a daily injection of insulin. A mother of two daughters, a victim of diabetes, also appeared on the program, which was built around an interview with Dr. Henry T. Ricketts, associate professor of medicine, University of Chicago School of Medicine, and Dr. Chester Coggeshall, associate in medicine at Northwestern University Medical School. Both doctors emphasized the need for careful training of the patient so that he understands the nature of the disease and the importance of balancing food, insulin and energy output. A second program in the series dealing with birthmarks is being planned.

### Chicago

**Society News.**—The North Side Branch of the Chicago Medical Society, meeting January 6 at 8 p. m. at the Drake Hotel, will hear Dr. Robert W. Keeton, Chicago, speak on "Types of Uremia and Their Treatment" and Dr. Ovid O. Meyer, Madison, Wis., on "Present Status of Treatment of the Anemias."

**Dr. Phemister to Give the Fenger Lecture.**—Dr. Dallas B. Phemister, chairman emeritus, department of surgery, University of Chicago School of Medicine, will deliver the thirteenth Christian Fenger Lecture of the Institute of Medicine of Chicago and the Chicago Pathological Society January 10 at the Palmer House, on "Circulatory Disturbances of the Skeletal System."

**Library Memorial Fund.**—Northwestern University has received a fund of $10,000 in memory of the wife of Ronald J. Chinnock, Chicago. Income from the gift will be used for benefit of the Archibald Church Library of the medical school. Purchase and maintenance of books on the subject of cancer, degenerative diseases and allied medical fields were recommended for special attention in the administration of the fund.

**Illinois University Appointments.**—Five appointments to the faculty of the University of Illinois College of Medicine have been announced. Dr. Lewis Haas, recently appointed assistant professor of radiology, served as head of the x-ray department of the Koranyi City Hospital in Budapest, Hungary, from 1945 to 1948 and held the rank of associate professor of roentgenology at the medical school of the State University in Budapest from 1946 to 1948. Nathan O. Kaplan, Ph.D., a research associate at Massachusetts General Hospital, Boston, has been appointed professor of the department of biological chemistry effective January 1. Dr. Kaplan was associated with the Manhattan project during the war. He is a graduate of the University of California at Los Angeles and received his Ph.D. degree in biochemistry from the University of California, Berkeley. Dr. Arthur A. Rodriquez has been appointed professor of physical medicine. A graduate of the University of Illinois, Dr. Rodriquez previously served as director of the fever therapy department of the Chicago Intensive Treatment Center. He was a Baruch fellow in physical medicine. Dr. Audrey Wilson has rejoined the faculty as an assistant professor of radiology following a year of residence in Phoenix, Ariz. A graduate of Northwestern University Medical School, she originally joined the faculty in October 1945. Dr. Max. C. Igloe, new head of Chicago Health Department's district health services division, has been appointed associate professor in the department of preventive medicine and public health on a part time basis at the University of Illinois College of Medicine. The new District Center at 802 South Paulina Street will be available to students of medical schools in Chicago for training in public health. Before joining the Chicago Health Department, Dr. Igloe served as chief of the outpatient section of the Veterans Administration Branch in Chicago.

## LOUISIANA

**Testimonial to Dr. Maes.**—In celebration of his seventieth birthday a testimonal dinner was given to Dr. Urban Maes by patients and friends in New Orleans October 29. Speakers included members of the faculty of the Louisiana State University School of Medicine and representatives of staffs and boards of trustees of Touro Infirmary and Charity Hospital. Dr. Maes retired as professor and head of the department of surgery and was appointed professor emeritus in 1947. He recently completed fifty years of practice at Touro Infirmary.

**Research on Diarrheal Diseases.**—A large scale research project on diarrheal diseases of infancy has been instituted at the Tulane University of Louisiana School of Medicine and Charity Hospital under the joint auspices of the departments of preventive medicine and pediatrics and the U. S. Public Health Service. Studies will be carried out on the bacterial and viral flora of the intestines of normal infants and alterations which occur with the onset of diarrhea. Methods by which the disease is spread from one infant to another and new forms of treatment will also be investigated. A team of physicians and nurses will be prepared to investigate such epidemics wherever they may develop throughout the South. Dr. James Watt, of the faculty and surgeon, U. S. Public Health Service, is director of the study. Dr. Myron E. Wegman, Dr. Robert L. Simmons and other members of the department of pediatrics and preventive medicine will be closely associated with several phases of the problem.

## MASSACHUSETTS

**Society Meetings.**—The Norfolk District Medical Society, meeting at the Boston Medical Library January 25, will hear three speakers discuss geriatrics, Drs. Theodore G. Klumpp, New York, and Robert T. Monroe and John Homans of Boston. At their meeting February 23 there will be a symposium on thromboembolic disease with Drs. William C. Moloney and E. Everett O'Neil, both of Boston, and James M. Evans, New York, taking part.

**Massachusetts General to Construct Research Building.**—Massachusetts General Hospital, Boston, announces plans for the construction of a $2,750,000 research building to permit consolidation and expansion of its research program. Construction is expected to start immediately after completion of plans April 1. Research will be conducted in cooperation with Harvard Medical School, Boston, and the Massachusetts Institute of Technology, Cambridge. The new building will contain psychiatry, pathology, cardiovascular and cancer laboratories, clinical laboratories for arthritis and endocrinology and research laboratories for biochemistry, enzyme chemistry, routine chemistry, cellular biology, experimental pathology and physics.

## MISSISSIPPI

**Personal.**—Dr. Felix J. Underwood, Jackson, state health officer, is the recipient of a plaque as an "award for meritorious service as campaigning chairman for the state division of the American Cancer Society in its 1948 campaign."

**More than Fifty Years of Practice.**—In a service at Baptist Church in Raymond, Dr. Frank G. Goodwin, Hinds County physician for fifty-nine years, was presented a certificate by the Mississippi State Medical Society and other tokens of appreciation from the church for his service to the community. Dr. Goodwin is a graduate of the Medical Department of Tulane University of Louisiana, 1889. He has practiced in the Raymond community for forty years.

**Student Scholarship Loans.**—Sixteen young men have been conditionally approved for medical education loans by the State Medical Education Board. Fifteen of this midyear group are veterans of World War II. One will attend Emory University School of Medicine, Atlanta; the others, the University of Mississippi School of Medicine, University. These men are a part of the 164 who have been approved by the State Medical Education Board for these loans. Recipients of such loans agree to become family doctors in approved rural sections for two to five years, all students being obligated for the minimum period of two years regardless of the amount borrowed.

## MISSOURI

**Personal.**—Dr. Clyde W. Geiter, Kansas City, has been appointed vice president of George A. Breon & Company, manufacturers and distributors of pharmaceutic preparations, Kansas City. Dr. Geiter was appointed medical director early this year. He is a graduate of Creighton University School of Medicine, Omaha, 1941.

**Dr. Foster to Direct Pharmacology Department.**—Dr. Robert H. K. Foster has been appointed professor and director of the department of pharmacology at St. Louis University School of Medicine, replacing the late Dr. John Auer, who died April 30. Dr. Foster received his M.D. degree from the University of Chicago in 1935, and formerly was chief pharmacologist with Hoffman La Roche, Incorporated, Nutley, N. J.

## NEW YORK

**Warning of Thefts of Narcotics.**—Dr. Herman E. Hilleboe, state health commissioner, issued a warning December 8 to hospitals, pharmacists and physicians to take greater care in guarding narcotic drug supplies. There have been more than twenty major thefts of such supplies from state hospitals during the last year in New York City, Buffalo, Troy, Syracuse, Rochester, Schenectady and Jamestown. He suggested prompt installation of suitable storage space, adequate protection of doors and windows leading to stockrooms, keeping working stocks at a minimum and returning working drug stocks to protective storage when drugs are not in active use.

### New York City

**Extend Diagnostic Service to Physicians.**—To make possible extension of the health department's diagnostic services to physicians, a pilot clinic is being established at the Lower West Side Health Center on Ninth Avenue in Manhattan. The clinic is expected to accept each month about 300 new ambulatory indigent patients on referral of physicians. The results of all examinations and laboratory studies and summary of the case with comments will be sent to referring physicians to whom the patient will be instructed to return.

**New Cancer Research Unit at Columbia.**—Columbia has announced plans to construct a $2,000,000 cancer research unit at the Columbia-Presbyterian Medical Canter. Three floors of new laboratories will be constructed atop the present Vanderbilt Clinic and will be in continuity with the existing laboratories of the medical school and in close relationship to the wards of Presbyterian Hospital. Work is to begin early in 1949 and is expected to be completed in 1950. The National Advisory Cancer Council will provide $1,000,000.

**Course in Medical Records.**—A course in medical records will be presented at the Columbia-Presbyterian Medical Center February 1 to March 17, 7-8:40 p. m. Tuesdays. The course will deal with the unit medical record and with requirements and problems peculiar to the system. It also aims to acquaint the student with The "Standard Nomenclature of Disease and Standard Nomenclature of Operations." Tuition is $40. Application should be made to the Director of University Admissions, Columbia University, 116th Street and Broadway, New York 27.

**Venereal Disease Control Program.**—The first phase of the venereal disease control program initiated by the Department of Health November 8 has been described as "an unqualified success" by Dr. Harry S. Mustard, Commissioner of Health. The number of persons coming to the city's social hygiene stations for the first time was two and one-half times the normal total, an increase of 10,000 during the month. Requests by doctors and hospital outpatient departments for free penicillin for the treatment of early syphilis, syphilis in pregnancy and gonorrhea rose 400 per cent during the month of the campaign, as compared with October, the first month during which the drugs were made available, "a proof of the cooperation of private physicians." Three million leaflets and 75,000 posters telling of advanced technics of treatment, emphasizing clean living and urging examinations, were distributed. Five county medical societies gave full endorsement to the program.

## PENNSYLVANIA

**Dr. Wolffe Wins Award.**—The Laymen's Honor Award of the Pennsylvania Association for Health, Physical Education and Recreation was conferred recently on Dr. Joseph B. Wolffe, of the Wolffe Clinic in Philadelphia at a December dinner meeting of the association. Dr. Wolffe becomes the fifth winner of the annual award, which is restricted to persons not actively or regularly engaged in physical education or recreational work. Dr. Wolffe and his associates conducted an extensive cardiovascular study of athletes.

### Philadelphia

**University Appointment.**—Dr. Wilbur C. Thomas, assistant professor of pathology at the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., has been appointed associate professor of pathology at Temple University School of Medicine.

**Dedicate Betatron.**—The betatron laboratory at the University of Pennsylvania was dedicated December 6, and will be used by the university's department of physics in its research program carried on jointly with the Office of Naval Research. Capable of accelerating electrons to 22,000,000 volts, the betatron was installed in a specially constructed laboratory at a cost of more than $200,000.

**Health Survey of Philadelphia.**—A citywide health survey of Philadelphia, conducted by the Health and Welfare Council, is expected to start this month. The survey will be directed by Dr. Carl E. Buck, New York, who has made many other surveys. The work will be carried out under the general supervision of an executive committee appointed by the City Planning Commission, the Philadelphia Department of Public Health and the Health and Welfare Council. Information gathered will be of particular interest to the department of health as a basis for carrying out a program for the decentralization of city health services.

## TENNESSEE

**East Tennessee Heart Association.**—The Knoxville Academy of Medicine initiated the formation of the East Tennessee Heart Association, organized November 17 primarily as a lay group. Its purpose is to promote research in heart disease in conjunction with the American Heart Association.

**Cerebral Palsy Center Opened.**—The Cerebral Palsy Center, Knoxville, established through the cooperation of the Tennessee Society for Crippled Children and Disabled Adults, the Elks, St. Mary's Memorial Hospital and the Cerebral Parents Council of Knoxville, opened in September in St. Mary's Memorial Hospital. The Knoxville Elks provided the fund of $10,000 to establish and maintain the center.

## GENERAL

**Social Hygiene Day.**—The American Social Hygiene Association has set February 2 as National Social Hygiene Day with the theme "Protect the Family . . . Stamp Out VD." The day will be observed in thousands of cities at meetings, rallies, institutes and forums on February 2, and throughout the rest of the month. Program and publicity aid materials may be secured now by writing to the American Social Hygiene Association, 1790 Broadway, New York 19.

**Heart Disease Research Grants.**—To encourage urgently needed research into the heart diseases, the American Heart Association invites application for fellowships and grants in the cardiovascular field. Application blanks are available from the association's medical director, Dr. Charles A. Connor, 1775 Broadway, New York 19. The program of the Heart Association is closely coordinated with that of the National Heart Institute of the U. S. Public Health Service and with the Life Insurance Medical Research Fund.

**Complete Inventory of Nurses.**—At the request of the National Security Resources Board, the American Nurses' Association will direct a complete inventory of all professional registered nurses in the United States and its territories. Final tabulation is expected to be completed by June 1949. The National Security Resources Board is a permanent civilian agency reporting direct to the President of the United States. It is charged with formulating for the President plans and policies concerning industrial and civilian mobilization of the nation's man power in the event of war.

**Research on Alcoholism.**—The Research Council on Problems of Alcohol will award two grants-in-aid of about $2,500 each to the Biochemical Institute of the University of Texas at Austin, Texas, and to the University of Washington School of Medicine, Seattle, for fundamental research on the problems of alcoholism. The Texas award is the second granted within the past year to carry on the basic research of Dr. Roger J. Williams on the possible physiologic causes underlying problem drinking. The Washington award is to facilitate the research of Dr. Walter L. Voegtlin in the determination of possible allergic factors underlying chronic alcoholism.

**Dr. Rusk Receives Award.**—Dr. Howard A. Rusk received a meritorious award of the National Rehabilitation Association for outstanding service in the field of rehabilitation December 7. Dr. Rusk, who was wartime chief of the Army Air Forces' rehabilitation program, is professor and chairman of the department of rehabilitation and physical medicine at New York University College of Medicine, and an associate editor of *The New York Times*. He is also director of the new Institute of Rehabilitation and Physical Medicine of the New York University—Bellevue Medical Center, consultant in rehabilitation to the United Nations and a member of the Advisory Board of the Office of Vocational Rehabilitation.

**The Rising Birth Rate.**—According to the *Statistical Bulletin* of the Metropolitan Life Insurance Company the birth rate in the United States shows an increase in productivity among women past the prime of reproductive life, a reversal of the downward trend in evidence for many years. At the ages 35 to 39 the birth rate among white women rose more than one third between 1939 and 1946, i. e., from 42 per 100,000 to 57, after having fallen steadily from about 80 per 1,000 in the period immediately following World War I. At the ages 40 to 44 the rate has also shown an upward tendency in recent years. The rate for first births has increased almost continuously since 1933; it reached a wartime peak of 26 per 1,000 in 1942, declined in the next three years and rose to an unprecedented 27 per 1,000 in 1946, when the number of first births was 1,150,000. For both first and second children the birth rates in 1946 were considerably above the levels recorded a generation ago. The average age at which women have their first, second and third child has gone up almost a year since the 1930's. For the years immediately ahead, the outlook is that the birth rate among women having their first child will decrease gradually, paralleling the slow decline of the marriage rate.

**Communicable Disease Report.**—While the seasonal decline in poliomyelitis continues, above normal seasonal incidence persists unusually late in a few states, according to the U. S. Public Health Service. A total of 360 cases was reported for the week ending December 15, as compared with 440 for the previous week, 524 for the next earlier week, 132 in 1947, 241 in 1946 and a five year median of 133 for the respective corresponding weeks. Of the current total, one third (122 cases) were reported in California, 24 cases in North Carolina, 22 in Minnesota and 19 each in Texas and Iowa; this is 57 per cent found in these five states. The total to date is 27,032 as compared with 10,575 in 1947, 24,763 in 1946 and a five year median of 13,443 for the respective corresponding periods. The September death rate for poliomyelitis (based on a 10 per cent sample of death certificates) was 3.5 per 100,000 population, which is above the expectancy based on the trend in the past ten years, and the rate of 1.2 for the first nine months of the year is higher than any rate recorded for a corresponding period in the past decade.

Measles is being reported in epidemic proportions in some areas. The reported incidence increased from 5,345 cases for the preceding week to 6,337 for the week ending December 15, of which 42 per cent occurred in the New England and Middle Atlantic states. The current figure and the total since the average seasonal low week (week ended Sept. 4, 1948), 33,269, are above the figures for all corresponding periods since 1943 (8,161 and 41,442, respectively).

## CORRECTION

**d-Tubocurarine in Wax and Oil.**—In the article by this title in The Journal, Dec. 11, 1948, page 1087, the word "milligrams" throughout the article should read "standard units." Each cubic centimeter of this preparation contains 27 mg. d-tubocurarine chloride pentahydrate (equivalent to approximately 175 units) and 48 mg. of myricin (wax) suspended in peanut oil. The charts in the article are correct.

# Marriages

Richard R. Royer, Grosse Pointe, Mich., to Miss Carolyn Stewart Wander of Maplewood, N. J., in Orange, N. J., September 11.

Marshall Wayne Woodard, Asheville, N. C., to Miss Patsy Ruth Jackson of Man, W. Va., September 18.

Charles Elroy Llewellyn Jr., Richmond, Va., to Miss Sara Grace Eldridge of Fort Smith, Ark., September 25.

A. Irvins C. De Friez, Boston, to Miss Amey Amory, of Dover, Mass., in Wellesley, Mass., September 18.

Kelly Tilson McKee, Bristol, Tenn., to Miss Gladys Harvath at Lynchburg, Va., recently.

W. Robert Elghammer, Chicago, to Miss Doris Elizabeth Postlewaite of Palatine, Ill., recently.

Dyer Carlisle Jr., Birmingham, Ala., to Miss Fleda Frances Baines of Gordo, September 27.

Charles A. Hogben, Rochester, Minn., to Miss Ann Stanbery in San Francisco, recently.

# Deaths

**Hugh Smith Cumming** ⊕ formerly Surgeon General of the U. S. Public Health Service, died at his home in Washington, D. C., December 20, aged 79. Dr. Cumming was born in Hampton, Va., Aug. 17, 1869. His education was obtained at Symmes Eaton Academy and Baltimore City College. He was graduated from the University of Virginia Department of Medicine, Charlottesville, in 1893 and from the University College of Medicine, Richmond, 1894, in which year he entered the U. S. Public Health Service as assistant surgeon. In 1899 he was promoted to passed assistant surgeon and served as chief quarantine officer in the South Atlantic and San Francisco until 1906, when he became medical officer attached to the U. S. Consulate in Yokahama, Japan. While chief quarantine officer at Hampton Roads in 1911, he was promoted to surgeon, in 1918 to Assistant Surgeon General and in February 1920 to Surgeon General. Subsequently he made a study of the pollution of navigable streams which was followed by an investigation of coastal waters along the Atlantic seaboard. During World War I he was detailed to the Navy as adviser in sanitation and later was sent to Europe in charge of public health service activities relating to sanitation, returning troops and the resumption of trade. He then served as president of the Inter-Allied Sanitary Commission to Poland, from where he was recalled to the United States to assume the position of Surgeon General in 1920. In 1945, on his twenty-fifth anniversary as director of the Pan American Sanitary Bureau, he received the gold medal from the Republic of Guatemala. He was president of the National Board of Medical Examiners from 1934 to 1936, president of the Southern Medical Association, 1930, American Public Health Association, 1931 and in 1924 the Association of Military Surgeons of the United States, from which in 1943 he received the Gorgas Medal. He was the recipient in 1936 of the Hartley Gold Medal of the National Academy of Sciences and in 1944 the William Freeman Snow Medal from the American Social Hygiene Association. He had represented the United States as head of the American delegation at the Pan American Sanitary conferences at Lima, Peru, Havana, Cuba, and Buenos Aires, Argentina; in 1919 member of the Cannes Conferences and of the Advisory Committee of the League of Red Cross Societies, served as president of the fifth Pan American Conference of National Directors of Health and was a member of the American Delegation to the Immigration Conference in Rome. He was head of the American delegation at a meeting of the Office International d'Hygiene Publique, which proposed the new International Sanitary Treaty, and a member of the international meeting which proposed the Pan American Sanitary Code. He was a member of the Permanent Committee of the Office International d'Hygiene Publique, and a member of the health committee, League of Nations, since its inception and vice president for many years. Dr. Cumming received the decoration of Commander of the Legion of Honor of France and the decoration Commander with Star, Polonia Restituta (Poland), and had been tendered the Order Al Merito of Ecuador, the Order of Carlos Finley of Cuba and El Sol of Peru. He received decorations from Chile, Colombia, Dominican Republic, Haiti and Mexico. Dr. Cumming's administration of the Public Health Service is credited with completion of the federal quarantine system, inauguration of preimmigration examinations at American consulates, establishment of the national leprosarium at Carville, La., and national narcotic farms, the construction of eight marine hospitals and fostering scientific research.

The President nominated Dr. Cumming for a fourth term as Surgeon General, effective March 10, 1932. He retired from active duty on Jan. 31, 1936, having served as an officer of the U. S. Public Health Service for forty-two years, and as Surgeon General for sixteen years. In addition to duties directly connected with the Public Health Service, Dr. Cumming was a member of the Board of Hospitalization formed by the President for the purpose of making recommendations concerning the expenditure of funds for the purchase and erection of hospitals used by the Veterans Bureau. He was a member of the board of visitors of St. Elizabeth's, Garfield Memorial and Columbia hospitals, chairman of the Section on Public Health Organizations of the White House Conference on Child Health Protection, honorary chairman of the Section on Public Health and Medicine, Eighth American Scientific Congress and an honorary fellow of the American College of Surgeons, American College of Physicians, Royal Society of Medicine, London, National Academy of Medicine, Peru, and the National Academy of Medicine, Mexico. He received the honorary degrees of Sc.D. from the University of Pennsylvania in 1930 and LL.D from Yale University in 1933. Dr. Cumming was honorary professor at the University of Santo Domingo, honorary director of the National Public Health Service of Paraguay, member of the Medical Society of the Dominican Republic, member of the Sigma XI and other honor societies.

Dr. Hugh Cumming was, throughout his life, a firm supporter of the ideals of American medicine. He was forthright in his views and dependable in his actions. His friendships were innumerable and his loss is mourned by many great leaders of medicine who held him dear.

**Frank Henry Ewerhardt** ⊕ of Richmond Heights, Mo., assistant professor emeritus of physical therapeutics at Washington University School of Medicine, St. Louis, died at the Barnes Hospital, St. Louis, October 15, aged 71, of acute leukemia. Dr. Ewerhardt was born in Sheboygan, Wis., Jan. 25, 1877. In the early 1900's he went to St. Louis, where he became director of the gymnasium and athletics of Smith Academy. In 1904 he joined the staff of Washington University as director of physical training, a position he held until 1913. He received his medical degree from Washington University School of Medicine in 1910. In 1913 he joined the medical faculty at his alma mater as assistant in anatomy; in 1915 he transferred to the department of medicine and in 1922 received his first appointment in the department of physical therapeutics. From 1933 through 1946, when he retired, he was director of physical education and director of university health. Dr. Ewerhardt was a past president and member of the executive council of the American Congress of Physical Medicine, which in September 1948 awarded him the Gold Key for outstanding service in physical medicine. He was a fellow of the American Association for the Advancement of Science, a member of the board of the Registry of Physical Therapy Technicians and a past president of the American Society of Physical Medicine. During World War II he was the health officer in charge, U. S. Army Hospital, Washington University. Dr. Ewerhardt served as consultant in physical medicine rehabilitation to the Veterans Administration, branch office number 9, and to the Council on Physical Medicine of the American Medical Association. He was a member of the original American Board of Physical Medicine, having been certified in 1947, and in 1945 and 1946 of the subcommittee on physical therapy of the National Research Council. He was emeritus chief of physical medicine of St. Louis Children's Hospital, Barnes Hospital, McMillan Hospital, Maternity Hospital and Washington University Clinics. He was co-author of "Therapeutic Exercise," which was published in 1947. He contributed the chapter on the "Use of Heat and Cold" in "Principles and Practice of Physical Medicine" and the chapters on "Physical Exercise" and "Posture" in Glasser's "Medical Physics."

**Walter Clinton Jones** ⊕ Florence, Ala.; born in Chicago, May 2, 1874; Northwestern University Medical School, Chicago, 1902; specialist certified by the American Board of Pathology; past president of the Alabama Association of Pathologists; member of the Southern Medical Association, American Society of Clinical Pathologists and the American Association for the Advancement of Science; fellow of the American College of Surgeons; at one time on the faculties of his alma mater, University of Illinois College of Medicine in Chicago, Medical College of Alabama, Mobile, and the Birmingham-Southern College; served on the staffs of the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company in Fairfield, Bessemer (Ala.) General Hospital, Norwood, St. Vincent's and East End Memorial hospitals in Birmingham, Colbert County Hospital, Sheffield, and the Evanston (Ill.) Hospital; died October 27, aged 74, of heart block.

**Eldwin Roy Witwer** ⊕ Detroit; born in Blake, Ontario, Canada, Aug. 23, 1890; Detroit College of Medicine and Surgery, 1914; assistant professor of radiology at the Wayne University College of Medicine; specialist certified by the American Board of Radiology; councilor of the Sixteenth District of the Michigan State Medical Society; past president of the Radiological Society of North America; past president and for many years secretary and treasurer of the Detroit Roentgen Ray and Radium Society; member of the commission on public health of the American College of Radiology; member of the American Roentgen Ray Society; affiliated with the Harper, Children's and Cottage hospitals; died November 2, aged 58.

**Theodore C. F. Abel,** Chicago; Jenner Medical College, Chicago, 1903; for many years medical director of Abel Laboratories; died in St. Francis Hospital, Evanston, Ill., October 24, aged 79, of thrombophlebitis of the right leg and cardiac insufficiency as the result of injuries received in a bus accident.

**William Howard Allen,** Mansfield, Mass.; Harvard Medical School, Boston, 1894; member of the American Medical Association; past president of the North Bristol Medical Society; served during World War I; for many years member of the school committee and board of health; died recently, aged 80, of coronary thrombosis.

**Ralph Nordock Arnold,** Greenfield, Ind.; the Hahnemann Medical College and Hospital, Chicago, 1917; member of the American Medical Association; served during World War I; county health commissioner; died October 19, aged 56, of coronary occlusion.

**Charles E. Baker,** Marietta, N. Y.; Eclectic Medical College of the City of New York, 1882; died in Sullivan recently, aged 90, of myocarditis and arteriosclerosis.

**Cornelius B. Barry,** Woonsocket, R. I.; College of Physicians and Surgeons, Baltimore, 1907; state senator; died recently, aged 69.

**Frederic Huntington Bartlett** ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1905; specialist certified by the American Board of Pediatrics, Inc.; member of the American Pediatric Society; served during World War I; author of "Infants and Children: Their Feeding and Growth"; for many years affiliated with the Babies Hospital; died October 19, aged 76, of coronary occlusion.

**Munson Russell Bixel,** Bluffton, Ohio; Eclectic Medical College, Cincinnati, 1925; served as vice president of the Allen County Board of Health and member of the board of trustees of the Bluffton College; affiliated with Bluffton Community Hospital, where he died October 3, aged 52, of coronary thrombosis.

**Harriet M. Carbaugh,** Lansing, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1888; died October 7, aged 85.

**Hayes William Carlin,** Los Angeles; Northwestern University Medical School, Chicago, 1909; died in Seattle October 28, aged 62, of coronary occlusion.

**Scott Parker Child** ⊕ Kansas City, Mo.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; an Affiliate Fellow of the American Medical Association; past president of the Jackson County Medical Society; at one time vice president of the Council of Social Agencies; died in the Municipal Tuberculosis Hospital October 6, aged 81, of bronchopneumonia and tuberculosis of the lungs.

**William B. Cochrane,** Rochester, N. Y.; University of Buffalo School of Medicine, 1896; member of the American Medical Association; at one time health officer of the town of Brighton; served on the staffs of Genesee Hospital and Park Avenue Hospital, where he died October 21, aged 76, of arteriosclerotic heart disease.

**J. Thomas Coghlan,** Rochester, N. Y.; St. Louis College of Physicians and Surgeons, 1927; served during World War I; died October 25, aged 52, of coronary occlusion.

**Charles Joseph Cooney,** Oelwein, Iowa; State University of Iowa College of Medicine, Iowa City, 1895; formerly health officer; on the staff of Mercy Hospital; died October 11, aged 75, of arteriosclerosis and bronchopneumonia.

**Robert Fulton Elvington,** Lake View, S. C.; Medical College of the State of South Carolina, Charleston, 1912; member of the American Medical Association; died October 5, aged 62, of heart disease.

**Walter Rudolph Evans,** Jackson, Ohio; Starling Medical College, Columbus, 1896; past president of the Jackson County Medical Society; formerly county coroner; died in Holzer Hospital, Gallipolis, recently, aged 75, of carcinoma of the prostate.

**James Farrage,** Corona, Calif.; University of Southern California School of Medicine, Los Angeles, 1934; member of the American Medical Association; died October 4, aged 48, of heart disease.

**Jesse Rideout Grimes,** Dumont, N. J.; Harvard Medical School, Boston, 1899; served during World War I; for many years president of the board of health and school physician; affiliated with Holy Name Hospital, Teaneck, and the Englewood (N. J.) Hospital; director of Dumont Savings & Loan Association; died October 29, aged 73, of coronary disease.

**Charles Cotton Harrold,** Macon, Ga.; Columbia University College of Physicians and Surgeons, New York, 1902; member of the American Medical Association; fellow of the American College of Surgeons and the American Association for the Advancement of Science; past president of the Chattahoochee Valley Medical and Surgical Association; served overseas during World War I; affiliated with the Middle Georgia Sanatorium and the Macon City Hospital; director of Citizens and Southern National Bank; died October 11, aged 70, of coronary disease.

**Leo Eugene Hayes,** Richmond, Va.; Medical College of Virginia, Richmond, 1927; served during World War II; died in Phoenix, Ariz., recently, aged 53, of heart disease.

**Wiley De Barr Hickey** ⊕ Leipsic, Ohio.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; past president of the Northwestern Ohio Medical Association and the Putnam County (Ohio) Medical Society; veteran of the Spanish American War and World War I; formerly mayor of Leipsic; served on the staffs of Memorial and St. Rita's hospitals in Lima; died in Kutztown, Pa., recently, aged 73, of coronary thrombosis.

**George Howard Jantzen,** Brooklyn; Long Island College of Medicine, Brooklyn, 1947; intern at the Kings County Hospital, where he died recently, aged 25, of Landry's disease.

**James Johnston** ⊕ Los Angeles; M.B., University of Toronto Faculty of Medicine, 1884; M.D., Trinity Medical College, Toronto, 1884; an Affiliate Fellow of the American Medical Association; for many years a major-surgeon of the Sixteenth Regiment, Pennsylvania National Guard; served during the Spanish-American War; affiliated with the Hollywood Hospital; died in the Veterans Administration Hospital, West Los Angeles, October 27, aged 85, of arteriosclerosis.

**Marvin Lamb** ⊕ Jacksonville, Texas; Baylor University College of Medicine, Dallas, 1935; past president of the Cherokee County Medical Society; died recently, aged 43, of pneumonia.

**Louise Doddridge Larimore** ⊕ Greenwich, Conn.; Woman's Medical College of Pennsylvania, Philadelphia, 1915; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists; for many years pathologist at the Greenwich Hospital; died recently, aged 59.

**Max Lehman** ⊕ Glendale, N. Y.; Cornell University Medical College, New York, 1907; for many years examining physician for the Prudential Life Insurance Company; formerly on the staff of Bushwick Hospital in Brooklyn; died in Bethany Deaconess Hospital in Brooklyn, October 16, aged 68, of injuries received in a fall.

**George Clenon Overstreet** ⊕ Lakeland, Fla.; Emory University School of Medicine, Atlanta, 1917; served an internship and residency at the Detroit Receiving Hospital; member of the Southern Medical Association and the American Association of Industrial Physicians and Surgeons; affiliated with the Morrell Memorial Hospital, where he served as superintendent; died in the Tampa Municipal Hospital, in Tampa, September 14, aged 55, of subarachnoid hemorrhage.

**Frederick D. Reardon,** Bowling Green, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; University and Bellevue Hospital Medical College, New York, 1901; past president of the Warren County Medical Society and of the Third District Medical Society; medical examiner for Warren County during World Wars I and II; died in the Pewee Valley Sanitarium and Hospital in Pewee Valley, September 27, aged 71.

**Charles Henry Slosson,** Youngstown, Ohio; Homeopathic Hospital College, Cleveland, 1888; died in Cleveland September 30, aged 82, of carcinoma.

**H. Brooks Smith** ⊕ Bluffton, Ind.; Indiana University School of Medicine, Indianapolis, 1932; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; served an internship and residency at Indianapolis City Hospital; associated with the Cayler-Nickel Clinic; died October 18, aged 40, of malignant hypertension.

**Melvin Albert Vogtel,** Minneapolis; Rush Medical College, Chicago, 1916; died in Asbury Hospital recently, aged 56, of cerebral hemorrhage.

**Frances Theodosia McDonald Wallace,** Pittsburgh; University of Wooster Medical Department, Cleveland, 1896; for many years a member of the staff of Presbyterian Hospital, where she was a member of the board of trustees for many years; served a four year term on the board of trustees of the State Hospital; died October 1, aged 84, of arteriosclerotic heart disease.

**Hugh Herbert Williams Sr.,** Sparta, Wis.; Rush Medical College, Chicago, 1896; member of the American Medical Association; veteran of the Spanish-American War; health officer and police and fire commissioner; affiliated with St. Mary's Hospital; died in Minneapolis October 7, aged 79, of coronary thrombosis.

**Frederic John Woodhead** ⊕ Waukesha, Wis.; Milwaukee Medical College, 1906; served during World War I; a member of the original board of directors of the Waukesha Memorial Hospital; died recently, aged 68, of carcinoma.

**Julius Francis Zielinski** ⊕ Rochester, N. Y.; University of Buffalo School of Medicine, 1929; on the staff of St. Mary's Hospital; died suddenly October 13, aged 42.

*(From Our Regular Correspondent)*

Nov. 13, 1948.

### The Troubles of the National Health Service

From all over the country comes the cry of doctors' offices overcrowded by persons, many of whom have little or nothing the matter, seeking medical advice. What may happen if we have a winter epidemic of some kind is a nightmare for the physician. The demands for drugs and apparatus is excessive. For the first three months of the service the national bill for eye testing and spectacles amounted to nearly $4,000,000, for drugs $7,600,000 and for dentists, including dentures, $4,900,000. These figures do not include the cost of treatment and appliances provided through the hospitals.

A much greater fall than was anticipated has taken place in private practice, both general and special. Persons who were expected to continue as private patients have taken advantage of the free National Health Service. The Minister of Health, Mr. Bevan, congratulated himself on the number of persons of the middle class who were using the service, and said that for them a doctor's bill was often an expense that they could not afford. But he omitted to say that a great cause of their trouble was the confiscatory taxation continued since the war by the Labor Government.

An abuse of the Health Service has occurred the extent of which cannot be stated because of the secrecy of the practice. A woman obtains a prescription from a doctor for which she has little if any need. Perhaps she shams illness. She takes the prescription to a pharmacist and trades the prescription for cosmetics or other things which he sells. The pharmacist has no difficulty in getting payment for the prescription, as he returns it with those that he has dispensed. Both score over this fraud. The woman obtains her cosmetics for nothing and the pharmacist probably makes an increased profit on this sale of cosmetics.

### The Rush for Spectacles

The opportunity of "something for nothing" has produced a rush for spectacles under the National Health Service. This is so great that the time for an appointment with an optician to the issue of spectacles is at best about four weeks and at worst three months. The delay is mainly due to a shortage of lenses. There is also a shortage of skilled workers and of machinery for grinding. Before the period of the National Health Service the output of spectacles amounted to between 4,000,000 and 5,000,000 a year. The ophthalmic industry now places the demands at nearly 8,000,000 a year. The cost will amount to about $80,000,000 a year. It is believed that 40 per cent of the population will require some aid to vision.

### Treatment of Pulmonary Tuberculosis with Streptomycin

A committee appointed two years ago by the Medical Research Council to plan clinical trials of streptomycin in pulmonary tuberculosis has presented the most important report on this subject ever made in this country. The work was done by clinicians and pathologists in various hospitals, and comparison was carefully made with controls. Only once before has a drug been submitted to controlled trial in this unpredictable disease. This was in 1931, when the gold treatment was found to be unsuccessful. The present trial was restricted to persons aged 15 to 30 years with acute progressive tuberculosis of both lungs unsuitable for collapse therapy, a form hitherto treated only by rest in bed. Such cases are not common, but a trial of streptomycin was made at 7 centers in 55 cases, while in 52 similar cases the patients were treated by rest in bed alone. All the patients were kept in bed on the same general regimen, but the former group received 2 Gm. of streptomycin daily by intramuscular injection, usually for four months. The results were assessed after six months. By then 4 of the streptomycin-treated patients and 14 of the controls had died, a difference which would not have occurred by chance once in one hundred times. Considerable improvement was observed in 27 (51 per cent) of the patients treated with streptomycin, but in only 4 (8 per cent) of the controls. The probability of occurrence of such a difference by chance is less than 1 in 1,000,000. At the end of a year 12 streptomycin-treated patients and 24 controls were dead, and the percentage improved had risen to 31 in the controls, while in the streptomycin cases it remained much the same, 56. Toxic effects of streptomycin were never severe enough to necessitate cessation of treatment, though giddiness, nausea and vomiting were common.

The conclusion drawn is that streptomycin can be of great value in acute phthisis, especially in early cases before cavities have formed. But it is not a "cure" for pulmonary tuberculosis. In these trials no patient was freed from infection. Nor does it render other treatment obsolete. It must be used with discrimination. Under the treatment the ordinary streptomycin-sensitive tubercle bacillus is rapidly replaced by a resistant bacillus. This means that the drug may be effective only once during an illness, and the time to give it must be carefully chosen. For the community there is the danger that unsuccessfully treated patients may disseminate streptomycin-resistant bacilli to others, producing many cases which would not respond to treatment with streptomycin.

### New Institute for the Postgraduate Study of Ophthalmology

The Institute of Ophthalmology has been formed by the amalgamation of the three London ophthalmic schools—Moorfields, Westminster and the Central Eye Hospital. The institute has been opened as one of the federated institutes of the British Postgraduate Federation of London University. The amalgamation affords a wider scope for teaching and research. A rearrangement of the hospitals' joint facilities has freed for the use of the institute the buildings formerly used by the Central Eye Hospital. The amalgamated hospital is stated to be the largest eye hospital in the world. At the opening ceremony addresses were given by Sir John Herbert Parsons, Prof. Alan Woods, director of the Wilmer Institute, Baltimore, and Prof. H. J. M. Weve, head of the eye institute, Utrecht. The two latter conveyed the good wishes of American and European ophthalmologists. Postgraduate students will come to the institute from all over the world, as they did to its famous predecessors.

### Jongbloed's Mechanical Heart

In the beginning of 1948 Dr. J. Jongbloed, Professor of Physiology in Utrecht (Netherlands) published a paper in the *Nederlandsch Tijdschrift voor Geneeskunde* (92:1065, 1948) about his work on the mechanical heart and lung. The function of the artificial heart is to replace the organic heart temporarily. The surgical treatment of the heart might improve considerably if it were possible to empty the heart of blood completely or nearly so. As technically it is practically impossible to insert the pulmonary circulation into a mechanical heart system, the use of an artificial heart involves the use of an artificial lung. The whole device might also be used in lung operations, and also in cases of temporary dysfunction of the heart (diphtheria) or the lungs (pneumonia, etc.). The author believes that it is desirable to maintain the circulation in the whole subject, not just in the brain, because it is not sure that the tissue not perfused will not be damaged, if for any reason a longer use of the mechanical system would be necessary. In this method the heart and lungs are out of function, but their nutritive blood supply is intact, as well as that of the other parts of the organism. The continuance of the coronary circulation seems important for the heart muscle; this is a great advantage, with the disadvantage, however, that the coronary blood flow may cause difficulties during intracardial operations. For the rest it will not be impossible to overcome these difficulties.

In preliminary experiments Professor Jongbloed and his staff studied, in dogs with widely opened thorax, the behavior of heart and lungs when empty of blood for one or more hours during the artificial circulation. The results were satisfactory; both resume their normal functions immediately when the artificial device is stopped. In these experiments T shaped cannulas were inserted in the venae cavae and in the aorta; the venae cavae were clamped near the heart, so as to make sure that no blood enters the heart cavities from this side. The single branches of the T cannulas led to and from the artificial heart-lung system. By removing the clamps he could change over at will from the mechanical to the organic circulation, and vice versa.

In further experiments in dogs the procedure was as follows. A flexible catheter was inserted through the vena jugularis externa dextra into the vena cava superior and another through the vena femoralis dextra into the vena cava inferior. Further, a T cannula was brought into each arteria femoralis. By the right mechanical heart the blood is sucked from the venae cavae and pumped to the oxygenator. From here the left mechanical heart drives the oxygenated blood via the T cannulas in the arteriae femorales. Here the blood flows in the normal direction toward the hind limbs and in inverse direction toward the arcus aortae. The aortic branches are normally perfused, the coronary system included; the aortic valves remain constantly closed. The right mechanical heart must be adjusted by changing the stroke volume and frequency so that a maximum of blood is sucked from the venae cavae.

These experiments were very successful. They proved that it is possible to maintain a complete artificial circulation without the use of the animal's heart and lungs, and with only a small surgical procedure. During these experiments the spontaneous respiration of the animals could be totally obstructed without any sign of distress of the animal. If treated aseptically the dog survives and behaves quite normal.

On the basis of these promising experiments Jongbloed constructed a mechanical heart-lung system for future use in man. This apparatus functions semiautomatically, is reliable and has a capacity of more than 10 liters per minute. The oxygenator is of a rather new type; at a minute-volume of 4 liters the oxygen uptake is in the range of 240 cc. per minute; there is no hemolysis. With this new apparatus, the first in the world of the capacity necessary for use in man, a series of experiments is now in progress.

One is fully aware of the fact that many difficulties must still be overcome before the safe use in man is possible and that these experiments and this method and apparatus represent only the first steps on a difficult path. The necessary anticoagulant, for example, may give great trouble. To be absolutely sure that no blood from the venae cavae enters the heart cavities during a heart operation these vessels can be clamped and the blood from the coronary sinus has to be sucked away to clear the field. And so on.

But the first steps must first be taken if one wants to go a new way, and there is good hope that Professor Jongbloed's method and apparatus may prove to be a valuable contribution to the solution of the problem of artificial circulation in man.

### "Asiaticoside" Treatment in Leprosy, Experimental Tuberculosis and Lupus

P. Boiteau and R. Saracino have just published in the *Médecin Français* a preliminary note on the therapeutic effects of "asiaticoside." Boiteau, when director of the Tananarive Botanical Park, studied the plant Centella asiatica, the sap of which natives used with some success for combating leprosy. The Madagascar antileprosy service has carried on therapeutic trials, first with an extract of this plant and then with the purified substances. Grimes and other Tananarive doctors entrusted with the treatment of lepers with "asiaticoside" have seen an immediate improvement in patients not responsive to any other treatment, and, after a congestive period, disappearance of erythematous patches, softening and resorption of cutaneous and hypodermic leprous tubercles and regression of interstitial keratitis. When the posterior chamber was not involved, patients' vision frequently improved, or at least an important fraction of it. In neural leprosy, attenuation of neuritis and regression of anesthesia are seen. Hansen's bacillus disappears from the nasal mucus in the second week of treatment. All patients treated have been either cured or much improved; failures are the exception. According to these local practitioners, in patients with previous renal infections slight outbreaks of albuminuria and, rarely, hematuria may occur.

Encouraged by the effects of this product on leprosy, Boiteau and Ratsimamanga did research on experimental tuberculous infection in the guinea pig, which will be the subject of a further communication, but they report that in treated animals, even when they do not seem completely cured, only slight lesions are to be seen, whereas control animals show multiple nodular localizations and the viscera containing many tubercles. Later, Boiteau and Saracino began therapeutic tests with "oxy-asiaticoside," a product very soluble in water, prepared through oxydation of "asiaticoside" with permanganate. On account of the congestive effect noted at the beginning of the treatment with "asiaticoside," they have exempted pulmonary tuberculosis and used cases of lupus. Out of 8 patients under treatment, 6 have been improved and 2 are completely cured. The first recovery was in a woman 60 years of age who for twelve years had erythematous lupus of the face, with a large excavation of the nose. After exacerbation of the evolutive signs during the first three weeks, a regression became rapidly apparent; in less than two months recovery was complete; the recovery still persists after two months. The other case is of expanding and ulcerative erythematous lupus, lasting for fifteen years; the soft parts of the nose were destroyed, the upper lip and the right orbit ulcerated. The congestive effect became noticeable by the exacerbation of pain, but as soon as the ninth day epithelization set in and on the twenty-sixth day the lip was almost completely epithelized. In the course of the fifth week, two fresh ulcerations became apparent in the cicatricial tissue, which yielded to two weekly injections. Treatment is still continued, although the patient may be considered cured. No incident due to the treatment has been noted by the authors, no shock, albuminuria, hematuria or fever. Sometimes, they noted, within forty-eight hours after the injection, an impression of heaviness in the lower limbs and a slight fall of arterial pressure.

## THE FARRIS TEST FOR OVULATION

*To the Editor:*—Dr. Edmond Farris has published a number of articles on his rat test for determining the time of ovulation. His latest paper appeared in The Journal, Oct. 23, 1948. The essence of these reports is that by noting the degree of hyperemia of the immature rat ovary after injection of the patient's urine the day of ovulation (hereafter referred to as Farris's day of ovulation, or FDO) can be determined. To prove the accuracy of his method he presents data on patients who were inseminated by coitus or artificially on the FDO and who conceived during that same menstrual cycle. This clinical test of his method would be quite acceptable but for one omission. Dr. Farris does not state that the insemination depicted in his charts was the only insemination in the cycle, or that insemination occurred only in a single twenty-four hour period at the FDO. The omission of this statement vitiates the experiment and destroys the logic by which his conclusions are reached. Dr. Farris states that "coitus is interdicted during each testing period," which I understand to be the ten days or so preceding the FDO. When the rat test indicates ovulation, insemination is advised, and conception occurs during the cycle as his data show. So far, so good. But Dr. Farris then discusses this insemination which he advised as if it were indubitably the cause of the conception, and he refers to the date of such insemination as "the day of conception." If coitus also occurred later in the cycle (and there is no indication that it did not also occur later) it might well have been the fertile mating rather than the insemination which Dr. Farris selects as proving his point. Since no clear statement is made in his articles to the effect that insemination occurred at FDO and at no other time in the cycle we must assume that such other inseminations did occur and that one of them might have been fruitful. If we make such an assumption, then we must discard from consideration the 18 cases in which conception followed coitus. Thus, of the 27 original cases there remain the 9 cases of artificial insemination. Five of these were by "homologous donors" which I take to be a new term for husbands. These men were fertile, for conception ensued. But did it result from artificial insemination on FDO or from coitus later in the cycle? Since there is no way of telling we are left with 4 cases to consider, the artificial inseminations by donors. To tabulate them:

| Case | Average Cycle | Insemination | Interval Between Insemination and Next Expected Menses | Comment |
|---|---|---|---|---|
| P. W. (fig. 1).......... | 25 days | day 11 | 14 days | A. I. one day after lowest temperature |
| H. Z. (fig. 4).......... | 27 days | day 13 | 14 days | Temp. incomplete |
| F. P. (fig. 4).......... | 28 days | day 13 | 15 days | Temp. incomplete |
| H. K. (fig. 6).......... | 27 days | day 12 | 15 days | Temp. incomplete |

It therefore appears that artificial insemination was performed at the usual time of ovulation, namely fourteen or fifteen days before the next expected period. In only 1 case was the temperature graph complete, and in this case insemination took place on the day following the lowest temperature reading. Of the 27 cases presented this is the sole case which is unassailable and in which it appears certain that insemination on FDO can be fairly correlated with the temperature graph.

The data which Dr. Farris has exhibited do not justify the conclusions that "At least 40 per cent of conceptions took place before there was any change in temperature" and "the use of basal body temperatures for detecting the time of ovulation may serve as an aid in the treatment of infertility in women in about 45 per cent of cases."

Pendleton Tompkins, M.D.,
San Francisco.

*To the Editor:*—Relative to the comments of Dr. Pendleton Tompkins, it may be stated that in the 23 complete cases of the 27 reported, 4 conceptions resulted from a single donor insemination on the day of prediction; 5 resulted from a single insemination with the husband's specimen on the day of prediction. Two of these had coitus later, but within eight hours of the insemination. In these 9 cases, no other intercourse occurred at any time during the cycle. Ten other conceptions resulted from coitus on the predicted day, as follows: 5 from isolated coitus which occurred once only, and at no other time in the cycle; 2 from coitus performed twice within ten hours and at no other time in the cycle, and 3 from coitus performed twice within the twenty-four hour period of the predicted day of ovulation. The 4 remaining persons had coitus on the predicted day of ovulation. In addition to the first coitus, patient J. H. had coitus one, two and nine days later; patient J. K. had coitus five, six, nine, and eleven days later; patient H. R. had coitus three days later, and patient M. B. had coitus three days later.

In summary, in 19 of the 23 complete cases insemination was artificial or by coitus within a twenty-four hour period of the predicted day of ovulation, and at no other time during the entire menstrual cycle.

E. J. Farris, Ph.D.
The Wistar Institute
Philadelphia.

## COLOMBIAN MEDICAL FEDERATION

*To the Editor:*—I have the pleasure of communicating to you that in the last General Assembly of the Colombian Medical Federation I was designated Secretary of Confederative Relations. On taking charge of the development of this function in the headquarters of the National Office of the Colombian Medical Federation, I wish to assure you of the sympathetic sentiments which Colombian physicians have for the American Medical Association, and to express to you our hope that your Association will continue to advance in your consideration and solution of medical problems which are common to all of us. At the same time, it is a pleasure to me to present through you a cordial salute to the American friends who have worked so much for the ideals of confederation.

This is also an opportune occasion to emphasize the spirit of cooperation and solidarity which Colombian physicians have in connection with the Pan-American Medical Confederation and with each one of the professional associations of the continent which it represents.

I have the honor to inform you that the last General Assembly of the Colombian Medical Federation named the following officers: Honorary President, Dr. Calixto Torres Umana; President, Dr. Alberto Garcia Maldonado; Vice Presidents in Charge of Scientific Matters, Dr. Jose A. Jacome Valderrama and Dr. Gonzalo Montes Duque; Secretaries of Miscellaneous Subjects, Dr. Rafael Peralta and Dr. Jorge Vergara Delgado; Secretaries of Propaganda, Dr. Francisco Geneco Mozo and Dr. Rafael Lopez Ruiz; Secretaries of Confederative Relations, Dr. Jorge Camacho Gamba and Dr. Jose MariaBaena Lavalle; Secretaries of the Treasury, Dr. Pedro C. Rojas Buitrago and Dr. Marco T. Perilla B.; Secretaries of Finance, Dr. Alfonso Tarazona and Dr. Jose Pablo Leyva; Procurator, Dr. Laurentino Munoz.

J. Camacho Gamba, M.D.
Secretary of Confederative Relations of the
Colombian Medical Federation, Bogota,
Colombia.

## THE AGES OF PHYSICIANS IN THE UNITED STATES, 1940 AND 1948

FRANK G. DICKINSON, Ph. D.
Director, Bureau of Medical Economic Research
Chicago

The number of living physicians by states was recently reported by this Bureau in The Journal (**137:**1550 [Aug. 21] 1948). The punch cards being developed by the Bureau's staff now permit an analysis of the age distribution of living physicians in the United States. Cards have not yet been punched for all June graduates of medical colleges and there is an unavoidable delay in reporting of deaths. These two facts should be kept in mind in any interpretations based on the following statistics.

The total number of physicians reported herein, 199,745, is slightly different from the 199,755 included in the previous report because of subsequent changes in the physician population. Approximately three fourths of all living physicians are in active practice.

Table 1 shows the age distribution of physicians as of July 1, 1948, for the United States based on our current punch card file and the corresponding figure for 1940 as analyzed by the United States Public Health Service from the 1940 Directory of the American Medical Association. Percentage figures are shown in table 1. The ages for only 0.7 per cent of the physicians in 1948 are unknown, whereas 1.4 per cent were unknown in 1940. Excluding the physicians of unknown age, the percentage of all physicians under 50 years of age rose from 57.5 in 1940 to 60.2 in 1948; in the age group 35 to 49 the percentage rose from 31.4 to 36.5. The percentage of all physicians of age 70 and over rose from 8.3 to 11.2. For all age groups except 35 to 49 and 70 and over the 1948 percentages are lower. At this time the Bureau records do not reveal the number of all physicians in each age group who are in active practice. Later tabulations by the Bureau will present the activity distributions by age groups.

Table 1.—*Age Distribution of Physicians in the United States, 1940 and 1948*

| Age Group | 1940 * |  | 1948 † |  |
|---|---|---|---|---|
|  | Number | Percent | Number | Percent |
| Under 30 | 20,069 | 11.4 | 21,571 | 10.8 |
| 30-34 | 25,027 | 14.3 | 25,442 | 12.7 |
| 35-39 | 20,829 | 11.9 | 27,058 | 13.6 |
| 40-44 | 17,744 | 10.5 | 25,549 | 12.8 |
| 45-49 | 15,691 | 9.0 | 19,835 | 9.9 |
| 50-54 | 15,661 | 8.9 | 16,738 | 8.4 |
| 55-59 | 15,568 | 8.9 | 14,467 | 7.2 |
| 60-64 | 15,514 | 8.8 | 13,436 | 6.7 |
| 65-69 | 12,211 | 7.0 | 12.143 | 6.1 |
| 70-74 | 7,810 | 4.5 | 10.505 | 5.3 |
| 75-79 | 3,822 | 2.2 | 6,780 | 3.4 |
| 80 and over | 2,719 | 1.6 | 4,863 | 2.4 |
| Unknown | 2,481 | 1.4 | 1,358 | 0.7 |
| Total | 175,146 | 100.0 | 199,745 | 100.0 |
| Mean age ‡ | 47.8 |  | 47.5 |  |
| Median age | 45.8 |  | 44.4 |  |

* From data tabulated for individual physicians listed in the 1940 American Medical Directory by statisticians of the United States Public Health Service.

† Tabulated from 3-card file.

‡ Assumed 28 for under 30 and 85 for 80 and over; unknown excluded.

Prior to 1940 there had been a steady increase in the number of physicians graduating from our medical schools. As a result the distribution by age has not become stabilized even in 1948. This probably explains the relatively high percentage now in the age groups 35 to 49 and the low percentage in the age groups 50 to 69. The increasing longevity enjoyed by the general population in the United States is shared equally by the physicians, as indicated by the large percentages in the age groups 70 and over. The speed-up program of medical training during World War II is reflected in the relatively high percentages in the 35 to 49 age group.

The mean age of all physicians of known ages in the United States in 1940 was 47.8 years; by 1948 it had dropped to 47.5 years. The aging of the medical population and the changes in the age distribution have not been sufficiently great in the interval from 1940 to 1948 to cause any decided change in the average age of living physicians. The median age dropped from 45.8 years in 1940 to 44.4 years in 1948, indicative of the increasing number of medical school graduates since 1940. The median is more accurate than the mean in 1940 because an approximate age had to be assumed for the "80 and over" and "under 30" classes in calculating the mean.[1]

Table 2.—*Number and Median Age of Living Physicians by States and for the United States, 1948*

| State | Number | Median Age | State | Number | Median Age |
|---|---|---|---|---|---|
| Alabama | 2,227 | 48.1 | New Hampshire | 729 | 44.9 |
| Arizona | 794 | 44.4 | New Jersey | 6,578 | 43.2 |
| Arkansas | 1,728 | 53.2 | New Mexico | 497 | 46.9 |
| California | 16,045 | 45.2 | New York | 30,981 | 43.8 |
| Colorado | 2,216 | 45.5 | North Carolina | 3,367 | 43.4 |
| Connecticut | 3,267 | 42.8 | North Dakota | 464 | 48.5 |
| Delaware | 440 | 43.6 | Ohio | 10,173 | 44.4 |
| Florida | 2,925 | 49.5 | Oklahoma | 2,245 | 50.9 |
| Georgia | 3,126 | 45.5 | Oregon | 1,813 | 44.2 |
| Idaho | 470 | 45.0 | Pennsylvania | 14,742 | 43.0 |
| Illinois | 13,320 | 46.2 | Rhode Island | 1,034 | 44.6 |
| Indiana | 4,404 | 45.5 | South Carolina | 1,519 | 45.9 |
| Iowa | 2,034 | 49.7 | South Dakota | 515 | 48.7 |
| Kansas | 2,206 | 46.6 | Tennessee | 3,255 | 44.8 |
| Kentucky | 2,662 | 48.7 | Texas | 7,868 | 45.4 |
| Louisiana | 3,080 | 38.7 | Utah | 845 | 40.5 |
| Maine | 997 | 49.8 | Vermont | 583 | 43.3 |
| Maryland | 3,715 | 40.3 | Virginia | 3,333 | 44.5 |
| Massachusetts | 9,078 | 42.9 | Washington | 2,774 | 43.2 |
| Michigan | 7,173 | 43.8 | West Virginia | 1,834 | 47.7 |
| Minnesota | 4,290 | 41.0 | Wisconsin | 3,870 | 44.8 |
| Mississippi | 1,507 | 52.9 | Wyoming | 253 | 46.5 |
| Missouri | 5,345 | 47.5 | District of Columbia | 4,118 | 41.7 |
| Montana | 539 | 46.1 | United States | 199,745 | 44.4 |
| Nebraska | 1,066 | 49.3 |  |  |  |
| Nevada | 201 | 49.3 |  |  |  |

Detailed age distributions for each state are not presented herein. The available supply of medical service cannot be measured by crude numbers of living physicians, since they include interns and residents still in training and physicians not engaged in the active practice of medicine due to retirement and special appointments such as teaching, administration, government service and research. An adequate inventory of medical service must also include an evaluation of the contributions of the large force of technicians and medical assistants who enable the modern physician to render far more medical service than was possible only a decade ago.

The state is too large an area for measuring the available medical service personnel. For example, in Utah the heavy concentration of population, hospital and training facilities and physicians in the area of Salt Lake City modifies state figures to an amazing degree and distorts the picture for those living in the large rural areas distant from this important metropolitan center. This accurate analysis of medical service must await the completion of the medical service area study now being made by the Bureau. At that time the punch card records will be sufficiently complete to furnish meaningful data on the age characteristics of the physician supply for areas of proper size in relation to the medical trading habits of the population. There are, of course, many interesting variations in the age distributions of the physicians in different sections of the United States which will be presented by the Bureau in studies now in process and in others being planned.

Subject to the limitations stated, certain interesting facts about the distribution of physicians by states are given in table 2, which shows the number and median age of living physicians in each state. Probably the median ages of physicians in the several states would exhibit a much more uniform pattern if interns, residents and physicians who are not in active practice were excluded. We are led to this conjecture by the observation that the higher median ages generally are observed in the sparsely populated states. The lower median ages occur in those states where there are a large number of medical schools and hospitals and, consequently, a large number of young physicians holding internships and residencies; this situation occurs primarily in metropolitan areas.

---

[1] Ages 28 and 85 were assumed to be the mid points of the two open-end classes, below age 30 and 80 and over for the 1940 data. The 1948 data were available for each year and no mid points were assumed.

### CONCLUSIONS

The average age of all living physicians in the United States in 1948 is slightly lower than in 1940. The percentages under 50 and over 70 years of age have increased. On the whole the typical American physician is slightly younger today than was the typical pre-World War II physician. These facts reflect the relatively rapid increase in the number of physicians since 1940. The medical population has increased 14 per cent, while the total population increased only 12 per cent. Each new physician is destined to remain in the medical population approximately forty years.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Ruptured Intervertebral Disk from Repeated Trauma During Employment.**—The plaintiff filed a claim for compensation for total and permanent disability due to an accident suffered during the course of his employment. From a judgment denying his claim, the plaintiff appealed to the court of appeal of Louisiana.

The plaintiff alleged that he was employed by the defendant to work in its manufacturing plant and that while so employed he suffered a severe injury to his back, that he was accidentally injured while engaged in moving heavy alloy hoppers, which was a part of the duties of his employment, and that while pulling and straining and moving said hoppers he suffered the damage to the lower region of his back which resulted in the rupture of an intervertebral disk, which necessitated a major fusion operation. He further alleged that at the time of the accident he considered that he had suffered only a strained back and, for this reason, did not immediately complain to his employer but continued working in an attempt to perform the duties required of him, thereby suffering increasing pain and disability; that within a few days thereafter his back became so painful that he was required to take a sick leave for several weeks, and that, at this time, he reported to the first aid station maintained by his employer on the premises and told the employees there of this back condition; that he remained away from the job for a period of about twelve weeks and was placed in traction and given other treatment by Dr. Anderson and other physicians in New Orleans and Baton Rouge; that within a few weeks following the accident, he reported his condition to Dr. Beam, the regularly retained physician of the defendant, but that he did not make any claim for compensation at that time as he did not understand the nature and extent of his injury and did not know what the prognosis of his condition would be, and, in the meantime, he was receiving his full salary. Both the counsel for the plaintiff and for the defendant agreed that the trial judge dismissed the plaintiff's suit for the reason that he had failed to prove an accident arising out of and within the scope of his employment. The main question, therefore, was whether or not it was necessary for the plaintiff to show a single accident or act of trauma that could have caused the ruptured disk. The plaintiff contended that the testimony in the case conclusively showed that the injury was caused by a series of strains or repeated injuries which were due to the nature of the duties he was required to perform for the defendant.

The facts disclosed that the plaintiff was employed by the defendant in 1940 and that he remained in this employment until September 1945, during which time he did rather heavy manual work. He experienced no difficulty in performing his duties until approximately the middle of 1944 when, while pulling a hopper and putting a hydraulic jack under a hopper, a hot flash went down his right leg and it seemed as though his hip had jumped out of place. He said he was unable to walk for a few minutes. From that time until he terminated his employment in 1945, the plaintiff was under the care of about twelve or more physicians and was in and out of a number of hospitals many times. He underwent many infra-red ray treatments to the lower part of his back. He also underwent heat treatments and wore various braces. In August of 1945 he visited the Ochsner Clinic, where his difficulty was finally diagnosed as a ruptured intervertebral disk and in October of 1945 the disk between the fourth and fifth lumbar vertebrae was removed and a lumbar fusion operation performed. The plaintiff introduced the testimony of seven fellow employees and of a number of physicians who treated him at various times during 1944 and 1945.

After reciting and considering the evidence received in the case, the court of appeal concluded that it was established by the medical testimony that one performing labor such as the plaintiff performed for the defendant, and one having a congenital abnormality such as the plaintiff had, is more susceptible to trauma and, as a result, a ruptured disk than one whose labors are light or one who performs no manual labor at all. The doctors, continued the court, were also in accord that a ruptured disk could be caused by the ordinary performance of such duties as the plaintiff was required to do on various jobs he held while employed by the defendant, that is, that a ruptured disk could come about by repeated minor or small strains or trauma over a length of time. Clearly, said the court, as the plaintiff failed to establish a single strain or accident, his case must then of necessity rest on proof of repeated minor injuries or repeated trauma as a cause for the ruptured disk, which, the court concluded, we believe he has proved. "The testimony convinces us that he suffered a ruptured disk while at work for defendant." Accordingly, the judgment of the trial court denying the plaintiff's compensation was reversed.—*York v. E. I. duPont de Nemours & Co., 37 So. (2d) 68 (La., 1948).*

**Paternity: Variations from Normal Period of Gestation.**—The plaintiff sued for divorce on the ground that the defendant was pregnant at the time of their marriage by an act of intercourse with a person other than the plaintiff, that such fact was concealed from the plaintiff and that the marriage was therefore procured by fraud. From a judgment of the trial court refusing to grant a divorce, the plaintiff appealed to the superior court of Pennsylvania.

Under Pennsylvania law, said the superior court, fraud is a ground for divorce, but the plaintiff has the usual burden of proving his case by clear and satisfactory evidence, and unless there is a preponderance of the evidence in his favor the divorce must be refused.

The parties first met on Oct. 31, 1945, and were married on December 21, having been in each other's company once or twice a week in the meantime. A child was born to the defendant on July 31, 1946, two hundred and twenty-two days after the marriage, but she denied that she was pregnant at the time of the marriage, denied that she had ever had intercourse with any man other than the plaintiff and insisted that the plaintiff is the father of the child.

The plaintiff introduced no evidence to show the defendant's association with any other men, but relied on the statements of two doctors who testified as expert witnesses. One of these doctors, who saw the baby four days after its birth, testified that the normal period of gestation is from 270 to 280 days and that in his opinion the birth in question was a normal birth and the period of gestation normal. The other expert witness who testified on behalf of the plaintiff had never seen the baby but based his testimony on its case history. He testified that according to the description of the baby, its weight, its reactions after born and the care which was used at the hospital, it was his opinion that the baby was a full term baby and that it could not have been conceived after the marriage on Dec. 21, 1945.

The defendant, on the other hand, introduced testimony of the physician who had given her prenatal attention and delivered the child. He testified that he had made internal examinations of the defendant on April 2, April 25, May 23, "some date in June" and on July 25, six days before the birth of the child. In his opinion the defendant had been pregnant three months on April 2 when he first examined her. He was then asked, "Can you definitely say as a practicing physician, in the line of prenatal history and examinations of the patient and the examinations of the baby, that this was not a full term baby?" His answer was, "I would like to emphasize in the light of all three matters, that this was not a full term child in the light of prenatal examination and history of the case and the examination of the baby." He further testified that the "usual period of gestation of a full term baby" is "ten lunar months, nine calendar months or two hundred and eighty days" and "I could not tell and no one could tell whether it was a full term child or not from examination of the baby"; and a "non-full-term baby" can be a normal baby, as this appeared to be.

The court said that the qualifications of the three doctors who appeared as witnesses were not questioned but that the testimony of the doctor who attended the defendant for many months prior to the birth of the child and delivered it was entitled to far more weight than the purely expert opinion testimony of the others. On the basis of all the evidence the court was of the opinion that the plaintiff had not met the burden of proof entitling him to a divorce. Accordingly, the judgment refusing the divorce was affirmed.—*Kissell v. Kissell, 60 A. (2d) 834 (Pa., 1948).*

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

**National Board of Medical Examiners:** *Parts I & II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April, 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

**American Board of Anesthesiology, Inc.:** *Written.* July 15. Various locations. Final date for filing application is April 15. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Avenue, New York 27.

**American Board of Internal Medicine:** *Oral.* San Francisco, Feb. 8-10, 1949. New York City, March 23-25. Final date for filing application is Jan. 2. Philadelphia, June 1-3. Final date for filing application is Jan. 2. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

**American Board of Neurological Surgery:** *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

**American Board of Ophthalmology:** *Written.* Jan. 14. *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

**American Board of Obstetrics and Gynecology, Inc.:** *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

**American Board of Orthopedic Surgery:** *Part I.* Various Centers, April and May. Final date for filing application is Dec. 31. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

**American Board of Otolaryngology:** New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

**American Board of Pathology:** Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

**American Board of Pediatrics:** *Oral.* St. Louis, Feb. 18-20. Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

**American Board of Physical Medicine:** Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

**American Board of Plastic Surgery:** Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

**American Board of Psychiatry and Neurology:** *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

**American Board of Surgery:** *Written.* Various Centers, March 1949. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

**American Board of Urology:** Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

**Alabama:** *Examination.* Montgomery, June 28-30, 1949. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

**Alaska:*** Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

**Arkansas:*** Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 2-3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

**Colorado:*** Denver, Jan. 4-7. Final date for filing application is Dec. 18. Sec.-Treas., Dr. W. W. King, 831 Republic Bldg., Denver 2.

**Connecticut:*** Hartford, March 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

**Delaware:** *Examination.* Dover, Jan. 11-13. *Endorsement.* Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

**Georgia:** *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

**Guam:** *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

**Hawaii:** *Examination.* Honolulu, Jan. 10-13. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

**Idaho:** Boise, Jan. 10-12. Dir., Bureau of Occupational Licenses, Miss Estella S. Mulliner, State House, Boise.

**Illinois:** Chicago, Jan. 11-13. Superintendent of Registration, Mr. Fred W. Ruegg, State House, Springfield.

**Indiana:** *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

**Maine:** Portland, March 8-9. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

**Massachusetts:** *Examination.* Boston, March 8-11. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

**Minnesota:*** Minneapolis, Jan. 18-20. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Building, St. Paul.

**Montana:** Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

**Nebraska:*** *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

**Nevada:** Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

**New Hampshire:** Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

**New Jersey:** *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

**New Mexico:** Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

**New York:** *Examination.* Various Centers, Feb. 1-4. Sec., Dr. J. L. Lochner, Jr., 23 S. Pearl St., Education Bldg., Albany.

**North Carolina:** *Endorsement.* Raleigh, Jan. 17. Sec., Dr. Ivan M. Procter, 226 Hillsboro St., Raleigh.

**North Dakota:** *Examination.* Grand Forks, Jan. 4-7. Act. Sec., Dr. C. J. Glaspel, Grafton.

**Oregon:*** *Examination.* Jan. 5-7. *Endorsement.* Jan. 21-22. Final date for filing application is Jan. 3. Exec. Sec., Mr. Howard I. Bobbitt, 608 Failing Bldg., Portland.

**Pennsylvania:** *Examination.* Philadelphia, Jan., 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

**Puerto Rico:** *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

**Rhode Island:*** *Examination.* Providence, Jan. 6-7. Chief, Mr. Thomas B. Casey, 366 State Office Building, Providence.

**South Dakota:*** Pierre, Jan. 18-19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

**Texas:** *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

**Utah:** *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

**Vermont:** *Examination.* Burlington, Feb. 3-5. Sec., Dr. F. J. Lawliss, Richford.

**Washington:*** Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

**West Virginia:** Charleston, Jan. 3-5. Sec., Public Health Council, Dr. N. H. Dyer, Capitol Bldg., Charleston 5.

**Wisconsin:*** Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

**Wyoming:** *Examination.* Cheyenne, Feb. 7. Sec., Dr. Franklin D. Yoder, Cheyenne.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

**Alaska:** Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1931, Juneau.

**Connecticut:** New Haven, Feb. 12. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

**District of Columbia:** *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

**Florida:** *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

**Iowa:** *Examination.* Des Moines, Jan. 11. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

**Michigan:** *Examination.* Ann Arbor & Detroit, Jan. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

**Minnesota:** *Examination.* Jan. 4-5, April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

**Oklahoma:** Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

**Rhode Island:** *Examination.* Providence, Feb. 9. Chief, Mr. Thomas B. Casey, 366 State Office Building, Providence.

**Washington:** Seattle, Jan. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

**Wisconsin:** Madison, April 2. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Enzymatic Conversion of Cyanide to Thiocyanate. W. A. Himwich and J. P. Saunders.—p. 348.

Effects of Anticholinesterases on Direct and Indirect Stimulation of Striated Muscle. C. R. Lowe and R. Gesell.—p. 355.

Distribution of Potassium and Sodium Between Serum and Certain Extracellular Fluids in Man. B. P. Folk, K. L. Zierler and J. L. Lilienthal Jr.—p. 381.

### American Journal of Psychiatry, New York

**104:**753-832 (June) 1948

Role of Motivation in Recovery from Illness. P. R. Hawley.—p. 753.

Evaluation of "Sexual Behavior in Human Male." A. H. Hobbs and R. D. Lambert—p. 758.

Cerebral Blood Flow and Metabolism in Schizophrenia: Effects of Barbiturate Semi-Narcosis, Insulin Coma and Electroshock. S. S. Kety, R. B. Woodford, M. H. Harmel and others.—p. 765.

Schizophrenic Syndromes as Frustration Reactions. J. M. Neilsen and G. N. Thompson.—p. 771.

Cerebrospinal Fluid Studies in Advanced Dementia Praecox. C. E. Johnson Jr. and Georgia L. A. Johnson.—p. 778.

Follow-Up Report on Series of Posttraumatic Epileptics. A. E. Walker and F. A. Quadfasel.—p. 781.

*Group Psychotherapy as Adjunct Treatment of Epileptic Patients: Preliminary Report. A. L. Deutsch and J. Zimmerman.—p. 783.

Prediction of Huntington's Chorea: Electroencephalographic and Genetic Study. R. M. Patterson, B. K. Bagchi and A. Test.—p. 786.

Bromide Psychoses: Four Varieties. M. Levin.—p. 798.

Hospital Treatment of Involutional Psychoses. D. M. Hamilton and Gladys M. Ward.—p. 801.

**Group Psychotherapy in Epileptic Patients.**—Deutsch and Zimmerman report a plan for the rehabilitation of veterans with convulsive disorders. As part of this program, they introduced the group psychotherapeutic approach. The patients were divided into units of 20. The first half of the first three sessions was devoted to orientation of the patient. The material discussed included history and definition of epilepsy, causes of epilepsy, various types of seizures encountered, the modern treatment, the hereditary factors associated with the disease and the question of marriage of epileptic persons. The second half-hour was devoted to a discussion with the authors as mediators. Further sessions were taken over by representatives from the Vocational Rehabilitation Section, who advised the group as to the various occupational skills and aptitudes which were necessary in future employment. Further meetings were held with members of the patients' families so that they could learn how they could cooperate in relieving the anxieties and tensions resulting from family overconcern. Members of industry and various employment agencies were invited to discuss employability of the epileptic person and attitude of the employer toward the disease. The authors found that after this group therapy the patients were able to view their problems more objectively. They had less fear, anxiety and insecurity. They no longer felt that they were freaks, since there were others similarly afflicted. They were more reassured as to the possibilities of education and training. As the family was brought into the discussion, many of the patients' anxieties and concern in relation to the family were reduced. Employers were willing to work with the group.

Unusual Complication of Meckelian Diverticulum. C. G. Morlock and J. G. Bennett.—p. 153.

**Follow-Up After Subtotal Gastrectomy for Ulcer.**—During the decade 1936 to 1945, inclusive, 394 partial gastric resections were performed for peptic ulcer at the Presbyterian Hospital in New York. In analyzing the results St. John and his associates gained the impression that there are less immediate postoperative difficulties after the Hofmeister type of resection than after the Polya type. An effort was made in nearly every resection to remove two thirds or more of the stomach. The value of this report lies in the completeness of the record of what has happened to the patients after they have left the hospital. Over 80 per cent of the follow-up records are based on personal interviews, the remainder being the result of communication with patients who could not be reached for interview. Results were satisfactory in 336 of the cases; they were unsatisfactory in 37. There were 18 postoperative deaths, and in 3 cases the available data were unsatisfactory. Few of the patients with results called satisfactory were restricted in their diets; most of them smoked, and many indulged in alcohol. Their life and occupation were not interrupted by recurrence of ulcer symptoms. For persons under age 45, resection is a relatively safe procedure, the hospital postoperative mortality being about 1 per cent. In view of the high percentage of excellent results and the low mortality, and in view of the absence of studies based on long follow-ups in cases in which vagus resection has been performed, the authors lack the evidence to justify younger patients with ulcer to have vagus section performed. It is difficult to dictate the form of therapy that should be used in persons of the older age group whose ulcer is in the duodenum and in whom carcinoma is almost surely absent. If these patients bleed, their risk of death is relatively higher than in the younger age group. If their symptoms are intractable under a medical regimen, as they often are, one must consider either a different form of medical therapy or surgery. Whereas psychic factors undoubtedly play an important role in relation to ulcers, they have not interfered seriously in many cases in this series with the benefits of surgical treatment. Not a few patients who gave the impression of being psychoneurotic before operation lost this characteristic after being free of their pain or bleeding.

**Penicillin in Postoperative Treatment of Perforated Peptic Ulcer and Appendix.**—Brown and Andrus report on 42 cases of perforated peptic ulcers and 97 cases of perforated appendixes operated on at the Philadelphia Naval Hospital between Jan. 1, 1946, and June 30, 1947. Patients from the Veterans Administration and active duty personnel are included in the series. Since the vast majority of these cases were surgical emergencies, operation was performed by the surgical watch officer, usually a younger surgeon with experience comparable to that of a surgical resident. There was no rigid standardization of surgical procedure, but the postoperative treatment was rather uniform. With few exceptions penicillin was administered postoperatively; 100,000 units every two hours became the accepted initial postoperative dose. Penicillin was maintained at this dosage level for days or even weeks in those cases in which the slightest indication for continuation of therapy persisted. In a group of 42 ruptured ulcers there were 2 deaths, a mortality rate of 4.8 per cent. There were 97 perforated appendixes in a total series of 815 appendectomies. There was 1 death, a mortality rate of 1 per cent for the ruptured appendixes and 0.12 per cent for the entire group.

Ligament of Lockwood in Relation to Surgery of Inferior Oblique and Inferior Rectus Muscles. W. H. Fink.—p. 371.

**Pathogenesis of Myopia.**—Stansbury is of the opinion that the diversity and number of etiologic theories of the pathogenesis of myopia indicate that the problem has never been satisfactorily solved. It is difficult to account for the proposal of so many mechanical hypotheses, considering the extent of the possible pathologic changes in the myopic fundus. The author believes that too much emphasis has been placed on the element of axial elongation and that the other pathologic factors have been practically disregarded. He arrives at the conclusion that axial elongation of the eye beyond normal limits is not necessary to myopia. Near work has never been shown to cause myopia, either in school or in adult occupations. There is no proof that overcrowding, poverty, poor health, inferior or superior mentality or bad ocular hygiene can cause myopia. No mechanical basis for myopia has ever been substantiated. There is no evidence that congenital deficiency of the sclera, disorder of growth, imbalance of the extraocular muscles, endocrine dysfunction, or avitaminoses plays any part in the causation of myopia. The author recommends that two types of myopia be differentiated: (1) primary, or physiologic, myopia, and (2) secondary, or pathologic, myopia. Primary myopia is, as far as is known, a biologic variation of refraction and a healthy one. It includes myopia of both high and low degrees, the great majority of cases being of the latter type. It is not possible to say whether the axial length or the refraction of the media is at fault. Secondary myopia is the result of disease of the coats of the eye. It should not be called myopia at all, but this term is used because of long-established custom and because the true cause is not known. The differential diagnosis of the two forms rests on the observation of pathologic changes in the fundus. The relation of other diseases to pathologic myopia has not been determined. It is possible that they play a part in the production of secondary myopia. It is suggested that a low grade chronic choroiditis is the primary lesion in secondary myopia. A classification of myopia is essential for progress in statistical and clinical research on this condition. Differential diagnosis of the two types is of great importance clinically, in therapy and in prognosis. It will prevent the waste of many useful citizens as "myopic cripples."

**Surgical Treatment of Congenital Cataract.**—Owens and Hughes review observations on 148 patients with congenital cataract. They analyze the results of operations performed on 231 eyes at the Wilmer Ophthalmologic Institute between January 1925 and October 1943. Gross associated ocular defects were present in 129 of 231 eyes with congenital cataract. The visual results in these eyes were significantly poorer than in the eyes without such gross ocular defects. The visual results for the patients on whom the operation was performed before 2½ years of age were poorer than for those operated on after this. The visual results were essentially the same whether the congenital cataract was complete or incomplete at the time of operation. Linear extraction or discission with subsequent linear extraction produced better visual results than simple discission in the patients with no associated ocular defects who were operated on after 2½ years of age. Operative and postoperative complications were as frequent in the eyes without associated ocular defects as in the eyes with associated ocular defects. The number of secondary operations necessary to clear the pupillary space was higher after simple discission than after linear extraction or discission with subsequent linear extraction. Complications occur with the same frequency after the extraction of senile as of congenital cataract. The poorer visual results after extraction of congenital cataract are attributed to associated ocular defects.

**Q Fever in California.**—Lennette states that a field laboratory has been established for the study of Q fever in California. The causal agent of Q fever is a rickettsia, which etiologically places this disease in the group to which belong epidemic and murine typhus, scrub typhus, Rocky Mountain spotted fever, boutonneuse fever and rickettsialpox. Morphologically and tinctorially, Rickettsia burneti resembles the other rickettsiae, but in other respects it differs from them. Thus, the organism is filtrable; it forms large microcolonies strikingly similar to those seen with psittacosis virus in infected cells in the mouse spleen; it produces no soluble antigen, nor does it produce agglutinins to the "X" strains of Bacillus proteus; also, the rash seen with other rickettsial diseases is absent in Q fever. Because of these characteristics which set off the Q fever organism from the other rickettsiae, it was proposed by Bengtson, Steinhaus and others that the organism be placed in a new genus to be known as Coxiella. The incubation period is from fourteen to thirty-two days. The symptoms in the early stages of Q fever are not different from those encountered in many other febrile conditions and afford no means of distinguishing this disease from others such as influenza, brucellosis, the enteric fevers and meningitis. Laboratory examinations provide no assistance. A definite diagnosis of Q fever is made by isolation of the rickettsia through inoculation of blood into guinea pigs or by showing that complement-fixing antibodies develop during the illness. For the serologic diagnosis of rickettsial and virus diseases, two specimens of blood, one taken in the early, acute stage of the illness and a second taken later in the convalescent phase, are required, since diagnosis depends on the demonstration of the appearance or rise in titer of specific antibodies. Therapy is entirely symptomatic and supportive.

**Combined Antigens in Immunization of Infants.**—Fleming and his associates tried to find answers to the following questions: 1. Must immunizing preparations be given individually, or can they be combined in order to reduce the number of inoculations? 2. Will a mixing of materials adversely affect the immunizing properties of the individual components? 3. Is the reaction produced by a mixture likely to be more severe? The authors present observations on infants observed at the Child Welfare Association of Montreal. The average age of the infants was 4 months. It was found that the response to diphtheria toxoid is substantially enhanced when it is given in combination with pertussis vaccine or with pertussis vaccine and tetanus toxoid. The immunizing efficiency of pertussis vaccine is not appreciably affected by its use in mixtures containing diphtheria and tetanus toxoids. Satisfactory immunization with tetanus toxoid can be achieved when it is combined with diphtheria toxoid and pertussis vaccine. Severity of reaction following inoculation was not increased by the use of mixtures of antigens. Public acceptance of active immunization for infants will be increased if mixtures of antigens can be used.

**Streptomycin in Tuberculosis.**—Kincade and his associates review observations on 100 patients with various forms of tuberculosis who were treated with streptomycin. At first the dosage of streptomycin was 3 Gm. daily given in divided doses every three hours. This was later reduced to 2 Gm. and since Nov. 1, 1947 has been 1 Gm. daily, divided in two doses and carried on for eight weeks. The results with the higher dosage and frequent injections were not found to be superior to the present course of 1 Gm. daily. The patients have been followed for from two to ten months since the completion of the treatment. In a 2 year old boy with tuberculous meningitis a remission resulted after fifty-eight days of treatment with streptomycin, but six months later he showed signs of recurrence which again yielded to treatment with streptomycin. None of the other 6 patients with tuberculous meningitis are alive today. The authors feel that streptomycin is most successful in uncomplicated meningitis of children. Results are disappointing in adults with other tuberculous lesions, though life may be prolonged. In miliary tuberculosis it is most useful in the acute exudative type in which the antibacterial effect of streptomycin helps the patient's natural defensive processes to control the disease. When it is combined with ordinarily accepted forms of treatment some patients who formerly had a hopeless prognosis can be saved. It is also indicated to control fresh spread superimposed on chronic disease. But, since the suppressive effect of streptomycin is not permanent because of the development of bacterial resistance, administration should be timed to coincide with any surgical procedure contemplated. In chronic fibrocaseous tuberculosis unsuitable for surgery the use of streptomycin is justified only because of the symptomatic improvement which it produces. Streptomycin is definitely indicated in ulcerations of the larynx or bronchi. It is useful in the treatment of tuberculous sinuses, adenitis and gastrointestinal tuberculosis. In patients in whom streptomycin was used as an adjuvant to surgical treatment the results were most encouraging. By controlling acute spread it was possible to perform operative procedures on patients who could not have been treated surgically without streptomycin. In primary tuberculosis and in minimal lesions that can be controlled by other means streptomycin is not indicated.

**Excision of Pelvic Viscera for Advanced Carcinoma.**—Brunschwig presents an operation devised for the total excision of all pelvic viscera, en masse, for advanced carcinoma. One diagram shows levels of transection of ureters and of pelvic colon; another shows conditions at end of operation, indicating the area from which peritoneum has been stripped as well as pelvic viscera removed. The peritoneal stripping has extended above the level of the common and external iliac vessels. The midline colostomy is shown. Both ureters have been implanted into the colon a short distance above the colostomy. The operation was performed on patients with the most advanced stages of pelvic cancer—a procedure of desperation since all other attempts to control the disease had failed. Because of the advanced stage of their disease, it is not to be anticipated that many, if any, of these patients will survive for prolonged periods. Two patients among those who have survived, did experience periods of relief and return to almost normal existence, but then developed metastases and succumbed. Varying degrees of palliation have been attained, for which reason the procedure is deemed justified. The author summarizes the status, as of April 10, 1948, of 22 patients who underwent total excision of the pelvic viscera. None of the patients died during the operation, but 5 died during the postoperative period after an average of eight days. Thus the surgical mortality is less than 25 per cent. The operation demonstrates the extent to which modern preoperative and postoperative supportive treatment permits extensive surgery; that a colostomy with both ureters implanted into the colon above is a feasible procedure and affords a situation compatible with normal physical activity, and that complete deperitonealization of the pelvis may be carried out and the small intestines permitted to descend into it without subsequent development of intestinal obstruction.

**Common Duct Stones.**—Shepard says that other investigators have found choledocholithiasis in 13 to 20 per cent of all patients harboring gallstones and nearly 1 in every 4 persons with cholelithiasis has at necropsy been found to harbor a stone in the common bile duct. As more explorations of the common bile duct are undertaken more choledocholithiasis is revealed, but there is an inevitable higher incidence of residual common duct stone. Postoperative cholangiography should be used routinely before removal of the common duct drain, as lack of symptoms with the drainage system clamped is an unreliable index of presence or absence of residual stone. If residual common duct stones are found on cholangiography, the more conservative nonsurgical methods of removal should be tried. Irrigation of the common duct drain with solution, the instillation of 1:500 dibucaine hydrochloride solution and perhaps Best and Hickens' regimen may be tried. This consists of the use of antispasmodics, magnesium sulfate and olive oil by mouth, and T tube irrigation with isotonic sodium chloride solution followed by instillation of olive oil into the T tube in conjunction with large doses of bile salts orally. If nonsurgical measures fail to remove the stone, secondary choledochotomy and mechanical removal are necessary.

*Methylene Blue, an Antidote to Altitude Sickness. M. M. Brooks.—p. 298.

**Ruptured Intervertebral Disk from Acceleration.**—Shaw presents 2 instances of back injury appearing after exposure to positive acceleration. The first is a case of ruptured intervertebral disk proved at operation. The second, although not a proved case, presents the syndrome typical of ruptured disk. These cases have in common an awkward, flexed position of the back during a "pull-out." This is probably the reason that these men suffered injury from accelerations ordinarily considered well below the tolerance limit for back injury. Under positive acceleration this flexion would increase and result in severe strain on the posterior longitudinal ligament and its adjacent annulus fibrosis. At the same time the nucleus pulposus would be compressed and forced against these strained posterior supports. The likelihood of posterior herniation of the nucleus pulposus is great in these circumstances. The author stresses that it is advisable to maintain an erect spine during exposure to positive acceleration whether in curvilinear flight or in the ejection seat.

**Methylene Blue in Altitude Sickness.**—In the experiments described by Brooks the method used was to go by auto from about sea level at Lima to Morococho at 14,900 feet (4,542 meters), via La Cima at 15,600 feet (4,775 meters), in approximately four hours. At Morococho lunch was served, and after an hour or more the descent to sea level was again made. Twelve volunteers were taken for the first excursion without reference to any tests. Of these, 6 were given a capsule of charcoal as a control, and 6 were given a capsule containing 0.05 Gm. of methylene blue. Half of each group became ill irrespective of treatment, and the conclusion that a larger dose of methylene blue was indicated was tested in the next experiment. In the second excursion only those who had been ill were selected. They were given a capsule containing 0.2 Gm. of methylene blue before retiring at night and again 0.2 Gm. before ascending the mountains. This dose proved to be effective, as none became ill. There were two more trips of six subjects each, in which this dose of methylene blue was given to each of the fresh recruits, resulting in the absence of symptoms in each case. Methylene blue speeds up the rate of combination of hydrogen with oxygen, thus compensating for the reduction in oxygen pressure found at high altitudes.

**Nutritive Value of Flour.**—Westerman and Templeton conducted experiments on albino rats to determine the effect on growth, maintenance, reproduction and length of life of the use of whole wheat, enriched flour, enriched flour supplemented with other B complex vitamins and 80 per cent extraction flour in the diets. It was found that the whole wheat and the enriched flour did not support normal growth and reproduction in the rats when included in the diet as sources of the B complex vitamins, at either the 40 or 60 per cent level. The enriched flour in the diet at these levels promoted better growth than the whole wheat. The enriched flour supplemented further with the B vitamins supported better growth, maintenance, reproduction and length of life than the enriched flour alone. The addition of choline, pyridoxine and riboflavin to the enriched flour resulted in greater weight gains than the addition of choline and pyridoxine. When choline, pyridoxine and calcium pantothenate were added even better growth was obtained. The animals with additional riboflavin or calcium pantothenate in the diet lived long and showed fewer deficiency symptoms than those on the diet of enriched flour with only choline and pyridoxine added. Animals on diets with choline, pyridoxine, calcium pantothenate and riboflavin added to the enriched flour, and these vitamins plus thiamine, made excellent growth records. None of the animals on the test diets reproduced so well as those on the stock diets. When 80 per cent extraction flour was enriched at the same levels as patent flour it supported slightly better growth than the enriched patent flour.

Ruptured Ectopic Pregnancy Complicating Normal Intra-Uterine Pregnancy. J. Tiller.—p. 335.

**Skin Cancer.**—This report by Tice and White is based on a study of 358 cases of cancer treated at the University of Kansas Hospital from 1933 to 1945. The lesion was verified by biopsy. The chief etiologic factor of skin cancer seems to be chronic irritation such as contact with coal tar products, actinic rays, inclemencies of the weather and uncleanliness. That excessive exposure to actinic rays plays a part in the causation of skin cancer is proved by the higher incidence of skin cancer in the Southern states. In Fort Worth and Dallas 46 per cent of all cancer is primary in the skin; in Chicago 12.5 per cent is primary in the skin. The authors were impressed by the number of skin cancers in the blond men from the wheat fields of Kansas. There seems little doubt that actinic rays are an important factor. The 358 patients reviewed here had 363 skin cancers. Skin cancer may be cured by surgical methods, radium or roentgen rays, or by a combination of the three. A physician should use the method in which he is most proficient. The basal cell epithelioma showed a cure rate of 95.2 per cent and the squamous cell a cure rate of 79.7 per cent. The over-all cure rate was 90.5 per cent. The massive type of roentgen therapy not only is more effective than the fractionated type but also is more economical in time saved for both the patient and physician. Chronic radiation ulcer is the only significant complication of roentgen therapy. It occurred in 4.6 per cent of these cases and generally yielded easily to plastic repair.

*Automatic Attentive Breathing in Angina Pectoris. A. Friedell.—p. 875.
*Early Ambulation: Clinical Results and Prerequisites. K. A. Meyer, D. D. Kozoll and N. Capos.—p. 882.

**Breathing in Angina Pectoris.**—Friedell relates that a patient told him of the relief he had obtained from a severe attack of angina pectoris when his attention was suddenly diverted to a bird singing on a treetop nearby. After that experience he found that he could abort an attack at will or shorten one by actively pretending that he was "listening to a bird sing on a treetop," providing he promptly stopped whatever he happened to be doing at the moment and turned his attention to his breathing, while he endeavored to keep himself at ease and relaxed. As he demonstrated it, his technic consisted in a slowed and protracted inhalation, with his chest expanding slowly during inhalation. His exhalation was slow also. The author encouraged this patient to continue this practice, although at first he did not comprehend its significance. Later, a search through the literature on respiration and an analysis of the physiologic factors involved in the act of "listening to a bird" convinced him that "attentive respiration" may be valuable exercise in some heart ailments. The author presents observations on 11 patients. After his patients mastered attentive breathing, it gradually became automatic with them, and they would automatically turn to those exercises at the first approach of any sign of distress. His only control was to keep each patient under observation for at least four weeks or more, on medication, rest and sedatives, before teaching the automatic attentive breathing exercises.

**Early Ambulation.**—Meyer and his associates studied, in relation to early or late ambulation, the postoperative complications of 500 surgical patients after the performance of one of five standard surgical procedures: gastric resection, colon resection, cholecystectomy, hysterectomy and herniorrhaphy. There was a total of 98 complications among 500 patients; 28 of the complications occurred among the 250 patients who became ambulatory early and 70 among the 250 who became ambulatory late. There was a total of 13 deaths (included in the 98 complications), of which all but 1 occurred in the group with prolonged bed rest. Pneumonia not only occurred more frequently in the late risers but also was more often fatal. Postoperative wound infections, thrombophlebitis and distention showed a definite decline with early ambulation, whereas pulmonary atelectasis and cystitis did not. A significantly shortened period of hospitalization was seen for each of the procedures when followed by early ambulation. Discussing the surgical prerequisites for early ambulation, the authors point out that transverse incisions are to be preferred to vertical incisions in patients in whom early ambulation is contemplated. The reason for this is that the transverse incision has a lower incidence of evisceration, nerve destruction and herniation. The use of interrupted sutures is also important in the program of early ambulation, since the lines of tension are more equally distributed. The use of interrupted sutures is of more importance than the type of suture used. It is also advisable to inform patients before operation that they are to become ambulatory early. The use of spinal anesthesia is preferable, because it makes the patient more cooperative. Contraindications to early ambulation include shock, hemorrhage, generalized peritonitis, intestinal obstruction, wound evisceration or extensive wound infection, toxic states, cardiovascular complications, extreme debility and severe anemia.

**Serum Concentration of Penicillin.**—Hewitt and his co-workers present pharmacologic data concerning the use in man of crystalline procaine penicillin G suspended in oil. The following single intramuscular injections were employed: 1 cc. of procaine penicillin G in oil (300,000 units per cubic centimeter) and 2 cc. of procaine penicillin G in oil (300,000 units per cubic centimeter). Persons without evidence of impaired cardiac renal or hepatic function served as subject of the tests. The majority were women who had passed through labor or young men who recovered from acute illness. In a number of cases the preparations were employed in the treatment of various acute illnesses as the definitive form of therapy. It was found that the maximum serum penicillin concentrations obtained with procaine penicillin G in oil were distinctly lower than those following a similar dose of sodium penicillin G in peanut oil and beeswax. The concentrations following administration of the former preparation, particularly with a dose of 600,000 units, showed considerably more uniformity throughout the twenty-four hours following injection. A comparison of the serum penicillin concentrations obtained after a dose of 300,000 and 600,000 units of procaine penicillin G revealed the most characteristic difference to be a prolongation of a given effective penicillin level rather than an increase in the magnitude of the penicillin concentration during the early period after administration. Crystalline procaine penicillin G in oil was superior to crystalline sodium penicillin G in peanut oil and beeswax for maintaining an effective serum penicillin concentration for twenty-four hours after injection.

**Polyposis of Colon.**—Hoxworth and Slaughter point out that whereas polyps of the colon which occur singly or in small numbers are common, polyposis (adenomatosis) is relatively rare. The condition is of particular interest because of its familial and congenital aspects, the diffuse involvement of the colon and the tendency to malignant change at an early age. Seven new cases of polyposis are described, which bring to 35 the total reported in the American literature since 1930, in which attempts at surgical cure had progressed to the point of removal of portions of the large bowel. The only two methods resulting in cure were total ablation of the large bowel and external ileostomy, or total colectomy and ileosigmoidostomy (or ileoproctostomy) combined with fulguration of the lower segment. Total removal of the large bowel is the method of choice if there is evidence of carcinoma of the rectum or lower part of the sigmoid colon. Total removal might also be preferred if the rectum exhibits closely set polyps with hyperplasia, ulceration and secondary infection. The method which combines fulguration with surgical treatment was employed with considerable success in 17 of the 35 summarized cases. This method has been ruled out. The presence of cancer in nearly half of the cases indicates the close observation which must be accorded this segment if it is allowed to remain. The authors stress that early recognition of the disease and the increased amount of surgery that can be performed in one stage because of modern therapeutic adjuncts to intestinal surgery combine to give an improved prognosis in polyposis of the colon.

**Emergency Operation in Hemorrhage from Peptic Ulcers.**—Dunphy and Hoerr show that the availability of large quantities of blood for emergencies has influenced the treatment of severe hemorrhage of the upper part of the gastrointestinal tract and makes it desirable to reevaluate the place of emergency operation for this condition. The poor results of emergency surgery in the past, contrasted with the supposedly good results of nonsurgical management, have led to the belief that such cases are medical. The crux of the matter lies in the accuracy of the selection of patients for operation. The authors believe that the rate of bleeding is the decisive factor. If a stable circulation cannot be maintained with transfusions of 1,500 cc. of blood per twenty-four hours, spontaneous cessation of the hemorrhage is unlikely and emergency operation should be undertaken. Some patients with an exsanguinating hemorrhage are admitted in profound shock and respond slowly to transfusion, tending to revert into shock. If a patient is in shock on arrival at the hospital, or shows evidence of it while under treatment, he deserves the constant vigilance of a bedside team of internist and surgeon. If the hemorrhage does not seem to be controlled with blood transfusions of approximately 500 cc. every eight hours, an emergency operation is to be considered.

**Massive Hemorrhage from Gastroduodenal Ulcer.**—Stewart and his co-workers believe that the advantages of early surgical treatment of bleeding peptic ulcer deserve more serious consideration than in the past. Accordingly, since January 1947 an effort was made on their surgical service to evaluate a plan of management of acutely bleeding gastric and duodenal ulcers involving immediate blood replacement and early subtotal gastric resection. The study is still in progress. By early surgical treatment is meant gastric resection with removal of at least 80 per cent of the stomach within twenty-four hours of admission to the hospital. The only patients with acute massive hemorrhage into the upper part of the gastrointestinal tract not operated on are those refusing operation, those presenting evidence of primary blood disease with clotting defect or those with evidence of cirrhosis of the liver with esophageal varices. In case of doubt as to the source of bleeding, exploratory laparotomy is performed. Determination of blood volume and extracellular fluid volume is done within one-half hour after the patient is admitted to the hospital, and massive blood transfusion is started immediately afterward. Operation is carried out during the course of blood replacement. Thirty patients have been studied under the program just outlined. In 19 instances operation was performed, and in 11 instances nonoperative management was carried out, as the patients either refused operation or died of hemorrhage before operation could be started. In 2 of the 19 patients operated on other lesions were found, in one instance esophageal varices and in the other carcinomatous ulcer at the cardiac end of the stomach.

Only exploratory laparotomy was performed in these, and both patients made uneventful convalescence from the operation. The experiences to date suggest that the surgical treatment affords a better prognosis than nonsurgical management.

**Acid-Producing Substances in Congestive Heart Failure.**—According to Crutchfield and Wood, intermittent administration of acid-producing substances seems to be theoretically and practically more effective for inducing diuresis than their continuous administration. Apparent synergism between these substances and mercury or xanthine diuretics may be related to the combination of two influences, both acting primarily to increase renal sodium elimination. One must pay proper regard to the relative state of cardiac competency, to renal function, hepatic function when ammonium salts are to be used, and the state of extracellulary fluid and its electrolyte content before using acid-producing substances. The usual dosage is 8 to 12 Gm. of ammonium chloride in divided doses daily, four days out of each week. This provides 5.3 to 7.9 Gm. of chloride ion. The normal kidney can produce ammonia sufficient to cover 16 Gm. of chloride daily. This dosage combined with a basic ash diet containing more fruits and vegetables serves to provide a surplus of acid irons to the patients without any appreciable danger of uncompensated acidosis. A basic ash diet seems more rational than an acid ash diet in the treatment of congestive heart failure, since the latter diet is usually of higher sodium content. Nausea and vomiting and skeletal decalcification do not constitute major problems in the use of acid-producing substances.

**Streptomycin in Draining Tuberculous Sinuses.**—Nalls and Moyer used streptomycin in treating 42 patients who had draining tuberculous sinuses. Twenty-three patients, 19 Negro and 4 white, under the old regimen were given 1.8 Gm. of the drug intramuscularly daily in six fractional doses of 0.3 Gm. Nineteen patients, 11 white and 8 Negro, received 0.2 Gm. intramuscularly every four hours for five doses, or a total daily dose of 1.0 Gm. In 15 of the first group, the draining sinuses originated in bone or cartilage; 3 were from tuberculous glands and 2 developed after removal of a tuberculous epididymis. In 7 of the second group the sinuses originated about the rectum; 6 were from bone or cartilage; 4 followed epididymectomy, and 2 were in the chest wall following thoracoplasty. Twenty-one of the 23 patients under the old regimen have had complete closure of all their sinuses, and the sinuses have remained closed for a follow-up period of seven to twelve months following termination of treatment. Eleven of the 19 patients under treatment with the new regimen had complete closure of all their sinuses and in 8 the sinuses are rapidly closing. With the reduced dosage under the new regimen, the same results are being attained with a decided reduction or complete absence of the toxicity noted under the old regimen. Under the reduced dosage resistance of the tubercle bacilli to streptomycin does not develop as often or as quickly as under the old regimen. Under the reduced dosage, treatment given twice daily, which secures a higher streptomycin blood level peak, produces less resistance than the more frequent treatment of five injections daily with a smaller streptomycin blood level peak. The treatment routine advised at present is 1 Gm. daily, 0.5 Gm. twice daily, twelve hours apart, intramuscularly, and duration of treatment for thirty days after healing has taken place or for a total of one hundred and twenty days, whichever is shorter.

**Sulfadiazine in Meningococcic Meningitis.**—The Pages used sulfadiazine in treatment of 60 consecutive patients, 43 white and 17 Negro, 59 men and 1 woman with an average age of 26 years, who had meningitis and were admitted to a station hospital between December 1942 and June 1945. It was the sole specific drug used in 52 cases, while it was used in combination with antimeningococcus serum in 3 cases, with penicillin in 5 cases and with sulfanilamide, antimeningococcus serum and penicillin in 1 case. The patients received an average total dose of 7.75 Gm. of sulfadiazine intravenously and 49.3 Gm. orally for an average of 10.2 days of treatment. One thousand cubic centimeters of sodium lactate was administered intravenously, followed immediately by 5 Gm. of sodium sulfadiazine in 100 cc. of distilled water without removal of the needle. These two medications may be repeated in eight hours if the patient is unable to retain oral medication. When the patient is able to retain oral medication, 16 Gm. of sodium bicarbonate per day in divided doses of 4 Gm. each may be given in lieu of the intravenous administration of lactate and should be continued for at least forty-eight hours after discontinuance of the sulfadiazine. Forty-eight cases of meningitis were proved to be meningococcic by laboratory methods, while 12 were considered to be "clinical" with headache, nuchal rigidity, vomiting, fever and pleocytosis of the spinal fluid. Five cases were considered mild, 28 of moderate severity, while 27 were severe. All the patients recovered. Alkalinization of the urine prevents renal complications. Meningococcemia should be suspected in a patient with arthralgia and fever. Sulfadiazine is considered the drug of choice in the treatment of uncomplicated meningococcic meningitis.

**Reconstruction of a New Thumb.**—Hardin reviews the case of a man, aged 35, who had lost a thumb three years previously. A small viable well healed stump was present. A surgical reconstructive procedure was started. A pedicle graft was raised on the right abdominal wall. A modification from the routine method of inserting bony and cartilaginous graft was employed. The stump of the right thumb was opened with a dorsal triangular incision, leaving the normal palmar contour present at the base of the first metacarpal. The proximal fragment of metacarpal was hollowed out. The drilling was done at a forward angle to give the proper position to the newly fashioned thumb. A portion of rib and curved costal cartilage was removed. The bony portion of the rib was fitted into the hollowed socket of the first metacarpal. The lateral portion of the pedicle was now detached and the free end of the pedicle was hollowed out to receive the graft. The medial portion of the pedicle remained attached for blood supply. Later the pedicle was detached medially, and the distal end of the newly fashioned thumb was closed. Complete healing of thumb had taken place three weeks after the attachment of the pedicle to the hand. The patient is able to touch the midportion of the little finger. Sensation is gradually returning to the new thumb. Rotation, abduction and adduction are present in a useful range of motion.

**Prognosis After Surgical Treatment of Hypertension.**—Smithwick reports on 263 patients with essential or malignant hypertension treated surgically from 1938 to 1943. A thorough denervation of the splanchnic bed was performed in two stages spaced eight to ten days apart, the lumbodorsal (thoracolumbar) technic (Smithwick 1940) being used. The purpose of this communication is to discuss the present status of these patients, all of whom were operated on at least five and at most nine and a half years ago. This report deals with 256 patients, of whom all had reached the stage of continued hypertension and 99 per cent had cardiovascular disease, which was serious in about 80 per cent of the group. Most of them had failed to respond to other therapeutic measures. Male patients comprised 39.4 per cent and female patients 60.6 per cent of the series. The total mortality during the five to nine year period of observation was 31.2 per cent. The mortality among males was 34.3 per cent and for females 29.1 per cent. Survival curves following surgical treatment are compared with those of Keith, Wagener and Barker. The survival rate was higher in all groups in the surgically treated series. The status of the electrocardiograms in a group of surgically treated patients is compared with that of a control series reported by Canabal, Warneford-Thomson and White. The difference observed was also found to be significant statistically. With regard to symptoms, over 90 per cent of the patients who have so far been interviewed five to nine years after operation are improved in this respect. The effect of operation on the cardiovascular system has been indicated by comparing the changes in various vascular areas before with those noted five to nine years after operation with particular reference to eyegrounds, electrocardiograms, renal function and the vascular system as a whole. Of 120 patients in whom the retinal area was examined 40.7 per cent showed improvement, 39.2 per cent showed no change and 20 per cent were worse. For 125 electrocardiographically examined patients the corresponding figures were 42.3 per cent, 48.8 per cent and 8.9 per cent. For 114 patients in whom the renal vascular region was examined the figures were 28.9 per cent, 61.3 per cent and 9.8 per cent and for 100 patients in whom all vascular areas including the cerebral were considered the figures were 51, 12 and 37 per cent. Further comparison of surgically and nonsurgically treated patients is desirable, but experience so far suggests that surgical treatment has favorably altered the prognosis for many patients with continued hypertension and cardiovascular disease.

**Acute Uremia.**—Zondek points out that extrarenal uremia or "prerenal uremia" according to Fishberg and "renal anoxia" according to Maegraith and associates is probably the most frequent form of acute uremia. Extrarenal uremia is a nonspecific body reaction—i. e., a pathologic process met with in different diseases. The uremia in question is called "extrarenal" because it occurs in disease not primarily involving the kidneys. The renal failure in these cases seems to be of a functional nature; another and essential characteristic is its association with extrarenal azotemia, a process caused by increased endogenous breakdown of protein which can be diagnosed by symptoms such as an increase of nonprotein nitrogen in the blood in addition to a dissociation of the urea-sodium chloride excretion. Since burns, crushing, surgical shock, hepatic disorders and myocardial infection may cause extrarenal azotemia plus renal failure—that is, extrarenal uremia—the author suggests that primary renal disease may also cause this complex of symptoms. He presents a case which seems to prove this assumption. One of the 2 other cases reviewed is of extrarenal azotemia caused by general infection in a patient with chronic nephritis. The extrarenal azotemia and the chronic nephritis existed separately and did not interfere with each other. The third case is one of severe acute cholecystitis complicated by acute uremia. The urinary excretion, at least in the first three days, of only small amounts of urea in spite of a high urea level in the blood suggests that the renal insufficiency must have been rather severe. But a process of extrarenal azotemia, too, must be assumed. This, however, was not recognizable until, from the third day onward, the daily urinary excretion of urea rose (to 37 to 70 Gm.) while the urinary excretion of sodium chloride still remained low; the sodium chloride-urea ratio was up to 1:10. The author stresses that acute uremia occurring in cases of chronic renal disease may be of the type of extrarenal uremia. Extrarenal uremia represents the pattern for most of the cases of acute uremia. The term "extrarenal uremia" may be replaced by "acute nonspecific uremia."

**Fibrositis.**—Cyriax is in agreement with the practice of dividing fibrositis into a primary and a secondary form, but he is convinced that primary fibrositis is an imaginary disease, whereas the secondary form is a real entity. He concedes that with regard to primary fibrositis authoritative opinions have been backed by pathologic changes in excised tissues; he does not deny the occurrence of such changes but only their bearing on symptoms. The following preconceptions should be discarded: that muscle spasm denotes a disorder of muscle, that muscles in spasm are tender, that tenderness of muscle indicates a muscle lesion, that nodules or crepitus at a muscle are significant, that limitation of movement in more than one direction can result from a muscle lesion alone and that examination of conduction along a nerve suffices. The author further considers the physical signs and the subsequent history in patients hitherto regarded as suffering from rheumatic fibrositis. He discusses acute rheumatic torticollis, vertebroscapular fibrositis, brachial neuritis, pleurodynia, acute lumbar fibrositis (lumbago), chronic lumbar fibrositis (backache), gluteal and sacroiliac fibrositis, sciatica and anterior crural neuritis. The underlying principle of the treatment of primary fibrositis is to secure reduction of the intra-articular displacement causing the symptoms. The author shows that there is no controversy about the existence of four categories of secondary fibrositis. Under the heading of traumatic fibrositis he mentions tennis and golf elbow. The other three forms of secondary fibrositis are rheumatoid fibrositis, infectious fibrositis and parasitic fibrositis.

*Chronic Relapsing Pancreatitis: Some Notes on Its Pathology, Diagnosis and Treatment. R. E. Horton.—p. 226.

**Chronic Relapsing Pancreatitis.**—According to Horton there is a gradation of severity from the familiar acute pancreatitis to a less often recognized subacute pancreatitis, which is characteristically a relapsing disease. The clinical picture may be difficult to recognize and in typical cases closely resembles recurrent cholecystitis with gallstones. If the biliary investigation is negative a diagnosis of relapsing pancreatitis is possible and may be confirmed by estimating the serum diastase during an attack. Of 7 cases of relapsing pancreatitis which have been recorded in 1 the patient died in a more acute attack; 4 others were treated by cholecystenterostomy. One of these died after operation. The other 3 have been relieved, 2 completely and 1 incompletely. Two other patients remain under observation. During the acute attacks treatment should be conservative with bed rest, and morphine to relieve pain. The indications for operation would appear to be the relief of severe and recurrent pain and the prevention of a more acute and fulminating attack from which the patient might die. A fulminating attack can be prevented with certainty only by pancreatectomy, but this is an uncommon complication and does not warrant such a severe operation. Thoracolumbar sympathectomy, splanchnic block and external or internal biliary drainage are other interventions that have been suggested. The author believes that internal biliary drainage has a fair chance of curing the symptoms. Should this be unsuccessful thoracolumbar sympathectomy may be performed. Pancreatectomy, with its higher mortality rate and the disadvantage of making the patient diabetic, should be reserved for patients with severe pain, such as may be associated with pancreatic lithiasis, and which is unrelieved by other operative measures.

Radical Cure of Inguinal Hernia with Plastic Insert. W. Thompson. —p. 182.
Handkerchiefs in Transfer of Respiratory Infection. K. R. Dumbell, J. E. Lovelock and E. J. Lowbury.—p. 183.

**Latent Tetany Caused by BAL.**—The occurrence of cramp-like pains in the limbs and spasms of the fingers in a patient undergoing treatment with BAL (2:3 dimercaptopropanol) suggested to Russell and his associates that a state of latent tetany might be present, and the detection of Chvostek's sign on both sides confirmed this suspicion. The absence of alkalosis made it probable that the tetany was of low calcium or low magnesium type. A study of potassium, sodium, calcium, magnesium and inorganic phosphate levels in the serum in this and other patients and volunteer students was made after intramuscular injections of BAL. Studies of 13 patients and volunteers receiving doses of BAL between 0.75 and 6.11 mg. per kilogram of body weight revealed, besides toxic symptoms, a positive Chvostek sign in 7, of whom 1 also had a positive Trousseau sign. Of the remainder, 5 had cramps and other toxic symptoms, and 1 was free from symptoms. Serum studies suggest that the tetany may be of low magnesium and possibly also of low calcium type, because these kations either were rendered unavailable to the cells or were removed attached to BAL. All the symptoms of toxicity from BAL are capable of explanation as latent tetany. Calcium balance and magnesium balance studies are necessary to explain the metabolic disturbances. In doses of 3.4 mg. per kilogram of body weight daily for four days BAL gives great relief to sufferers from arsenic, gold and mercury intoxications, and the danger of a temporary unavailability of pericellular calcium and magnesium can be ignored if the patient is provided with a high calcium diet, magnesium sulfate and vitamin D. The serum sodium and serum potassium levels were not appreciably affected by the injection of BAL.

**"Sulphetrone" in Tuberculosis.**—Madigan says that in 1943 a clinical trial with "sulphetrone" (4,4'-bis [gamma-phenyl-N-propylamino] diphenylsulfone-tetrasodium sulfonate) was organized at the County Hospital of Farnborough, Kent. The choice of clinical material was dictated solely by its presentation within the hospital; thus it represents a statistically unselected population drawn on for five years. Pulmonary cases predominated, but all types of tuberculosis were included. A total of 70 cases were treated. Whether "sulphetrone" is given parenterally or by mouth, a gradual increase of dosage is necessary to build up therapeutic levels in the blood of 7.5 to 10 mg. per hundred cubic centimeters if toxic symptoms are to be avoided. It is also essential to give iron and brewers' yeast to avoid hypochromic and nutritional anemia. Even so a residual hemolytic anemia will arise, leading to a fall in hemoglobin concentration though not to below 60 per cent (Haldane). To avoid major toxic emergencies, seen when blood "sulphetrone" levels above 12.5 mg. per hundred cubic centimeters are allowed to persist, a scheme of management is suggested. No beneficial effect was detected from "sulphetrone" therapy of acute infections—e. g., acute miliary tuberculosis and tuberculous meningitis—but a patient with chronic miliary tuberculosis recovered. Improvement was observed in chronic lesions. Thus 12 out of 17 cases of acute pulmonary fibrocaseous disease and 13 of 22 cases of chronic disease improved. All of 4 cases of primary pulmonary tuberculosis, and 6 of 8 of strictly exudative lesions, improved. In the chronic hematogenous group all of 4 cases improved, and in productive pulmonary infiltrative group 3 out of 4 improved. In general, all exudative phases of infiltrative disease were halted and reversed by "sulphetrone." The need for long-continued courses is emphasized, units of observation being three months, and routine laboratory control is essential.

Intracranial Disorders of New-Born Associated with Birth. Kate Campbell.—p. 57.
Epidemic of Gastro-Enteritis in Infants, with Special Reference to Treatment. G. Stable and I. G. Philpott.—p. 63.
*Some Aspects in Management of Case of Jaundice. M. E. Chinner. —p. 69.

**Management of Jaundice.**—Chinner discusses various functional problems and reports a case to illustrate the procedure necessary to separate obstructive from parenchymatous jaundice. He considers the constant presence of urobilinogen and the failure to respond to vitamin K as valuable tests. A serum colloidal gold test should be performed. This will produce a strongly positive result in hepatogenous jaundice and a negative result in obstructive jaundice. A serum phosphatase test is also useful; this will produce a reading of over 30 units in the obstructive type of jaundice and of less than 30 units in the hepatogenous type. The most valuable tests for differentiating obstructive and hepatocellular jaundice are (1) the urinary urobilinogen test, (2) the serum colloidal gold test, (3) the serum alkaline phosphatase test and (4) the response of the plasma prothrombin time to vitamin K. Liver biopsy is valuable, but requires experience and must not be done if the prothrombin time is abnormal. The first requirement in the treatment of the jaundiced patient who has hepatitis is rest, and this must be maintained until the patient has completely recovered. In the acute stages this is not difficult, as the patient frequently feels ill, but in the more chronic forms of hepatitis it is easily proved that exercise will bring about a swelling of the liver and exacerbation of symptoms. When the patient is walking about avoidance of fatigue is essential. In the acute stage the patient will take only fluids with a high carbohydrate content; if the vomiting is severe, then dextrose must be given by the intravenous drip method. As the hepatitis becomes subacute, a high calory diet becomes necessary. In the past it has been thought that diets poor in or free from fat were a necessity; but recent opinion holds that such diets are undesirable, as they are poor in calories and unpalatable. Recently the author has been using gradually increasing amounts of fat. The author also gives vitamins of the B group, crude liver injections and dried brewer's yeast.

*Penicillin Treatment of Acute Hematogenous Osteomyelitis. E. E. Vuori and M. Sulamaa.—p. 547.
Intestinal Suction Treatment with Miller-Abbott Tube. S. S. Krook. —p. 562.

**Penicillin in Hematogenous Osteomyelitis.**—The material reviewed by Vuori and Sulamaa was collected from several hospitals. It comprises 83 cases in which 92 bones were involved. Ten patients were adults and the remainder children below 17 years. The infecting organism was determined in 60 patients; in 2 streptococci were found; in 1 both streptococci and staphylococci; in 1 Staphylococcus albus and in the remainder Staphylococcus aureus. The treatment varied considerably in the different hospitals. Treatment with penicillin was often commenced rather late. One patient died probably because of insufficient dosage of penicillin. In the majority of cases the effect of penicillin on the general infection at the initial stage was good. The disease became chronic in spite of the treatment with penicillin in 42 cases, and did not heal until sequestrectomy or radical trepanation had been performed. The treatment with penicillin gave better results in the cases of primarily chronic disease than in those of acute disease; it was more effective in the cases which showed principally osteoplastic roentgenologic bone changes than in those showing principally osteolytic changes. No significant correlation could be proved between the recovery and the intensity of the treatment with penicillin and the time of its commencement. The fact that the group of cases in which treatment with penicillin was given within the first week of illness contained a significantly larger number of cases of the osteoplastic type than the group which came under treatment later indicated that it is important to aim at early treatment. Patients treated with smaller doses had a lower frequency of complications.

**48:281-338 (July) 1948**

Answer to Report by Professor Van Gehuchten on Hemolytic Serum Therapy in Multiple Sclerosis. M. Laignel-Lavastine and N. T. Koressios.—p. 281.
*Contribution to Study of Deficiency of Intelligence in Patients with Parkinsonism as Sequela of Lethargic Encephalitis. R. Nyssen and M. Wens.—p. 287.
Systematized Nervous Diseases and Problems of Heredity. L. van Bogaert.—p. 308.

**Deficiency of Intelligence in Patients with Parkinsonism.**—Nyssen and Wens studied the intelligence of 69 adults, 50 men and 19 women, with postencephalitic parkinsonism by submitting them to four different tests. Each test consisted of eight problems which had been given previously to 175 normal adults, working men and women and housewives. A deficiency of intelligence was demonstrated by these tests in the majority of the patients. Each of the normal controls as well as each of the patients was tested individually. The degree of difficulty in solving every single problem was established statistically in the controls. These statistical norms made it possible to compare the average of the results obtained in the patients with that of the results obtained in the controls; these norms also warranted an approximate estimate of the incidence and of the degree of the decrease in intelligence of the patients with parkinsonism. By these methods of examination it has been ascertained that the majority of patients with postencephalic parkinsonism present a certain degree of deficiency of their intellectual capacity in its strict sense, a deficiency which may reach the level of manifest oligophrenia. By various grouping procedures it has been possible to observe that the age of the patient at the time of the tests and at the time of the acute infection or the duration of Parkinson's syndrome and the coexistence of psychopathic or psychotic disorders hardly correlate with the degree of deficiency of intelligence. In contrast to that, there seems to be some causal relationship, or at least a reciprocal relation, between the intensity of Parkinson's syndrome and institutional treatment of the patient on one side and the degree of the decrease in intelligence on the other side.

*Intramedullary Nailing and Free Bone Chip Plastic. H. Hellner.—p. 241.
Method of Roentgenographic Demonstration of Brain Abscess by Contrast Medium: Preliminary Report. H. Kolmer.—p. 247.
Contribution to Symptomatology of "Megacolon" with Particular Consideration of Megasigmavolvulus from Malnutrition. W. Hartkopf.—p. 250.
Problem of Overbridging Severe Nerve Lesions. B. Hummel.—p. 253.

**Intramedullary Nailing and Bone Chip Plastic.**—According to Hellner, the effectiveness of intramedullary nailing in genuine pseudarthrosis should not be overestimated. Results in 19 cases of genuine pseudarthrosis, 6 of the humerus, 3 of the forearm, 5 of the femur and 5 of the leg, showed that exact immobilization with the exclusion of all mechanically unfavorable influences is indispensable in addition to intramedullary nailing. Bone autotransplants are required for traumatic pseudarthrosis. Twenty-one cases, 10 of the humerus, 7 of the radius, 2 of the ulna, 1 of the femur and 1 of the leg are reported. The bone plastic is far superior to simple intramedullary nailing as well as to that combined with excision. The bone transplant must be prepared in a carpenter-like fashion, and it must be rammed in, folded in or pinched as a carpenter does it. The simultaneous employment of Küntscher's nail is dispensable, because a plaster of Paris cast is to be applied in every case and because later on the nail must be removed anyway. Küntscher's nailing and autotransplantation do not exclude one another. In no case was the taking of the transplant disturbed by nailing and that in pseudoarthrosis as well as in osteoma and in congenital pseudarthrosis. Reduction osteotomy may be carried out with the nailing technic; dehiscence must be avoided and the fragments must be brought in close contact. Küntscher's nail may be used satisfactorily for other types of osteotomy, likewise.

Dynamics of Insufficiency of the Left Heart. K. Blumberger.—p. 353.
Protein Metabolism During Nutritional Deficiency and During Restoration. H. W. Bansi and G. Fuhrmann.—p. 358.
*New Serum Phenomena During Postoperative Phase After Tonsillectomy. M. Frobenius and Elizabeth Völkel.—p. 368.
Paroxysmal Paralysis and Hyperventilation. W. Skalweit.—p. 371.

**Serum Phenomena After Tonsillectomy.**—The observations reported by Frobenius and Völkel were made on 2,000 patients who had undergone tonsillectomy. Since most of the operations were made on the basis of medical indications, postoperative observations were usually more prolonged than is usually the case in laryngologic departments. It has been suspected that during the postoperative phase processes take place in the serum which may be related to the course of serum disease. If in a healthy subject several intracutaneous wheals are produced with several different normal serums on symmetric locations of the skin of the back, it can be seen that all wheals remain of the same size and behave like a single wheal. If the same is done on a patient nine days after tonsillectomy, wheals develop which rapidly increase to about the size of a penny, are white like porcelain and are surrounded by a red areola with pseudopodia-like extensions. These wheals subside much less rapidly than those that form in normal persons. Such wheal tests were made on 25 patients on the ninth day after tonsillectomy and were repeated with one hundred and fifty different serums. All except one of the persons tested showed the same results. The experiment was repeated on another group of 25 patients on the twelfth day, and all 25 showed a "hyperergic reaction." Summarizing these and other observations, the authors say that during the postoperative period after tonsillectomy characteristic serum phenomena can be elicited which are analogous to the behavior observed after the injection of serum of a heterogenous species. This is the more noteworthy since hemolysins against sheep erythrocytes can be demonstrated in the blood of tonsillectomized patients. These observations suggest the existence of two antigen-antibody systems which develop during convalescence and determine its course. In addition an increase in the nonspecific reactivity of the skin is observed, the course of which is apparently related to the aforementioned processes.

*Direct Results of Vagotomy in Presence of Gastric Complaints Following Operation on Account of Ulcer. I. Boerema.—p. 1755.
Treatment with Penicillin Aerosol. E. L. Cardozo, M. C. van der Plas and M. van den Ban.—p. 1767.
Development of Large Papules in Scabies. G. Cremer and J. R. Prakken.—p. 1778.

**Vagotomy in Gastric Disturbances After Operation for Ulcer.**—Boerema reviews observations on 25 patients who previously had undergone surgical operations on the stomach, but in whom symptoms had persisted or returned and who on this account had been subjected to a transthoracic vagotomy. In 19 of these, in whom an earlier laparotomy had established the presence of an ulcer, vagotomy completely counteracted the symptoms. Among the 6 in whom the first operation had not disclosed an ulcer, but who had nevertheless been subjected to an operation on the stomach, there were 2 in whom vagotomy was successful; in 1 there was some improvement and in the other 3 vagotomy was ineffective. Thus vagotomy was effective in the presence of disturbance after gastric operation for ulcer, but not when no ulcer was present.

Investigation of Long Term Results of Rollier's High Mountain Treatment in So-Called Surgical Tuberculosis. P. Frank.—p. 1825.
*Evaluation of Electric Shock Therapy. A. Hutter.—p. 1830.
*Results Obtained in Tuberculous Bronchitis with Large Doses of Vitamin $D_2$, Gold Preparations and Streptomycin. C. Dijkstra.—p. 1835.
Gamma Globulin in Bacterial Infections. S. van Creveld.—p. 1845.

**Electric Shock Therapy.**—Hutter advises that electric shock treatment be carried out during institutional care rather than under dispensary conditions. In schizophrenia there has been a return to insulin and "metrazol" shock as more effective than electric shock, but electric shock has nevertheless symptomatic value, particularly in the presence of restlessness. Electric shock is definitely the most suitable treatment of endogenic depressions, irrespective of severity, duration or age of patient. Manic depressive patients over 70 years of age are usually still strong enough to withstand electric shock treatment. Close cooperation with the cardiologist is important in electric shock treatment and, when there is doubt, an electrocardiogram should be taken before electric shock is induced, but this is not necessary in all patients. The cardiologist will rarely forbid electric shock treatment, except in patients with disturbances in the cardiac conduction system or with serious myocardial changes. A general examination, which should precede the shock treatment, may reveal contraindications, but they are few. A melancholic patient who has diabetes can be subjected to electric shock treatment, even if he receives insulin.

**Large Doses of Vitamin $D_2$, Gold Preparations and Streptomycin in Tuberculous Bronchitis.**—Dijkstra stresses the importance of an early bronchographic and bronchoscopic examination in patients expectorating positive sputum who have no demonstrable cavity. If this is done tuberculous bronchitis is frequently found in these patients. The author presents a number of illustrative cases. These cases also show the favorable therapeutic results obtained with gold preparations, with vitamin $D_2$ and, in some cases, with streptomycin in extensive and severe tuberculous bronchitis.

*Prefrontal Leukotomy with Particular Attention to a Case of Compulsion Neurosis. M. Müller.—p. 97.
*Epileptic Attack, Sleep and Periodicity. K. H. Stauder.—p. 107.
Psychologic Investigations on Patients Who Have Sustained Brain Injuries. A. Busemann.—p. 120.
Psychology of Prisoners of War. M. in der Beeck.—p. 136.
Narcolepsy and Regulatory Disturbances in Central Nervous System. W. Skalweit.—p. 140.
Malaria Psychoses. P. Lowitzsch.—p. 146.
Polyneuritis After Bacillary Dysentery. A. Herrlich.—p. 167.

**Prefrontal Leukotomy.**—Müller reviews observations on 26 patients subjected to prefrontal leukotomy. The technic employed was that described by Freeman and Watts. No fatality resulted from the operation in these 26 cases. The author evaluates the results obtained in 20 cases in which more than six months had elapsed since the operation. One case, that of a woman, aged 80, who for fifty years had had a phobic obsession, is reported in detail. In this case the operation resulted in a peculiar change in the emotional life. Defense mechanisms lost their obsessive character and the woman was able to live with more composure and calm. Of the other 19 patients, 1 with paranoia was freed from his symptoms for several months, but, after that, silliness, excessive euphoria, loss of inhibitions and weakness of concentration became evident. Five patients were sufficiently improved so that they could be discharged into familial care. In 7 other patients there was a slight improvement, which rendered them more easily manageable in the institution. The other 7 patients remained uninfluenced by the operation, aside from brief improvement immediately after the operation. Müller concludes that leukotomy can never be a treatment with truly causal effect; but it leads to psychic release. The author warns against exaggerated optimism.

**Epileptic Attack and Sleep.**—Stauder shows that lack of sleep effects in many epileptic patients an increase in attacks. These epileptic patients show increased irritability. During the war the author observed that formerly well men, who had passed beyond the age when epilepsy becomes manifest, occasionally responded to extreme lack of sleep with epileptic attacks. Many of them exhibited the same sleep disturbances as did epileptic patients, anxiety states with motorisms and forms of tremor. The connections between epileptic attacks and sleep are supported by abnormalities in the sleep of epileptic patients such somnambulistic states, motorisms during sleep and disturbances in the waking mechanism; relation between postepileptic sleep and the time of the next attack; the recurrence of attacks during certain hours of the night, and the effect of hypnotics and stimulants on the epileptic attack. In contradistinction to Economo, the author regards postepileptic sleep as comparable to true sleep, particularly because it has a considerable restorative effect. During the advanced stages of epilepsy sleep is insufficiently restorative, and this partly explains the progression and change in the personality. Comparison of bioelectric brain processes during sleep and during attacks throws more light on epileptic sleep phenomena.

Spondylarthritis Ankylopoietica. Review. L. Brahme.—p. 1375.
*Antihistamine Treatment in Allergic Diseases. Experimental Basis. Å. Nilzén.—p. 1382.
*Antihistamine Treatment in Allergic Diseases. B. Arner.—p. 1386.
Atrial Flutter in Old Persons. H. Buch and T. Fløystrup.—p. 1399.
Treatment of Cancer of Stomach During Twenty-Year Period. C. Brynjulfsen.—p. 1402.

**Antihistamine Treatment in Allergic Diseases. Experimental Basis.**—Investigations to date indicate histamine to be a factor of decisive importance in anaphylaxis and allergy. Histamine is most likely released by the antigen-antibody reaction. Experimental anaphylaxis reactions in animals and experimental allergy reactions in man can be prevented by drugs antagonistic to histamine. Nilzén says he has demonstrated that urticaria and eczematous reactions can be lessened or prevented by the use of antihistamine.

**Antihistamine Treatment in Allergic Diseases.**—Arner reports that treatment with antihistamine had good or appreciable effect in 15 of 29 cases of allergic rhinitis (10 with residual symptoms after earlier antiallergy treatment, 5 of untreated mild rhinitis), good effect in 4 of 14 not desensitized cases of hay fever and in 16 of 24 desensitized cases, no effect in 19 of 25 cases of bronchial asthma and uncertain effect in 6, good effect in acute urticaria, good or appreciable effect in 6 of 19 cases of chronic urticaria and good effect in 11 of 12 cases of serum sickness. Secondary by-effects were rare and mild. Specific desensitization is superior to treatment with antihistamine preparations alone, but antihistamine affords relief in cases with residual symptoms after specific desensitization. The effect of antihistamine during specific desensitization as studied in 35 cases was inferior to that of epinephrine; use of antihistamine during specific desensitization did not seem to hasten desensitization. Evaluation of some of the results of antihistamine treatment published is difficult because it is not clear whether or not other antiallergic treatment was also given and the effects of the antihistamine are not classified.

*Acute Leukosis in First Year of Life.* R. A. Marquézy and P. Royer.—p. 113.
*Present State of Vaccination and of Serum Therapy Against Whooping Cough. F. Verliac.—p. 126.
Clinical Aspect of Diphtheria of Infants in Course of Epidemic of 1945-1946. R. Sacrez, P. Beyer, T. Uhl and Miss A. Sagot.—p. 139.

**Vaccination and Serum Therapy Against Whooping Cough.**—According to Verliac, the new concepts of prophylaxis and treatment of pertussis in the United States hold out hopes of a wider employment in France of vaccination and serum therapy the practice of which so far has been rather limited. The effectiveness of vaccination within the first six months of life has not yet been demonstrated beyond doubt. Vaccination, therefore, is suggested of children at the age of 6 months; it may confer immunity about the ninth or the tenth month of life. The following year the injection should be repeated in case of possible contamination. Biologic tests, such as the determination of agglutinins and opsonins, and particularly the agglutinogen skin test, make it possible to distinguish children who are susceptible to the disease from immunized children and thus to determine the effectiveness of the vaccination. When contact is suspected, and as soon as possible after that, prophylactic injection of human or rabbit antipertussis serum should be given to a child which has not been vaccinated. Highly satisfactory results from the same serum in cases in which diagnosis of pertussis has been established demonstrated the usefulness of this serum particularly in extremely young children or in those with pulmonary complications. These methods of treatment must be combined with the usual measures of hygiene and with symptomatic treatment. Systemic treatment with streptomycin or treatment with streptomycin aerosol is suggested for grave cases of pertussis.

*Blastomas of Mesenchyma of Bones. D. Brachetto-Brian.—p. 285.

Action of Rutin on Capillary Fragility and Permeability. A. Pavlovsky and H. Castellanos.—p. 309.

**Blastoma of Mesenchyma of Bones.**—Brachetto-Brian reports clinical, roentgenologic, pathologic and therapeutic observations on 38 cases of so-called blastoma of bone mesenchyma. These tumors originate in the reticular tissue of the bone marrow and should be termed reticuloblastomas. The malignant type is highly metastatic, involving, most frequently, the bones. The disease is fatal in three to seventeen months after appearance of the early symptoms of tumor. The sensitivity of the tumor to roentgen rays depends on the variety of the tumor, which, according to the author, can be (1) syncytial, (2) lymphocytic, (3) angiovascular and (4) xanthocellular. The syncytial variety is represented by tumors of the type of Ewing's sarcoma. These tumors have the histologic structure and potential capacity of evolution of mesenchymal tissue and a marked sensitivity to roentgen rays. The lymphocytic variety includes the greatest number of cases of malignant reticuloblastoma (the classic lymphosarcoma of bones). These tumors show histologic changes with serial transitions of syncytial reticuloblastoma into highly differentiated lymphosarcoma. The angiovascular variety of tumor may be benign or malignant. Benign tumors in this group are recurrent, whereas malignant tumors are moderately malignant. The angiocellular type is stubbornly recurrent, even after the most ample surgical resection. The xanthocellular variety is rare. Tumors of this variety are either benign or malignant. The malignant form can be compared to systemic xanthosarcoma. It is the form in which metastases to the bones are most frequent.

*Treatment of Abscess of Small Pelvis by Local Injection of Penicillin. D. Stucki.—p. 790.

**Local Penicillin Treatment of Abscess of Small Pelvis.**—Stucki treated 4 women between the ages of 27 and 51 with abscess of the pelvis of genital origin, by local injections of penicillin. The first patient had suppurating streptococcic parametritis with a fistula well encapsuled and surrounded by a fibrous wall and resistant to intensive treatment with penicillin and sulfonamide drugs for three months. Closure of fistula and disappearance of the tumor were obtained after four local injections of 100,000 units of penicillin within eight days. Definite recovery was demonstrated on examination within six months. Satisfactory results were obtained in the second patient with acute gonococcic pyosalpinx to whom four local injections of 200,000 units of penicillin were given. The local treatment was reinforced by systemic treatment with 160,000 units of penicillin daily for eight days. Recovery occurred, but an adnexal tumor persisted. Clinical recovery was obtained in the third patient with parametritis due to streptococcus and staphylococcus. Suppuration was controlled with five injections of 100,000 units of penicillin, but the abscess was transformed into an infiltrated mass which required three additional local injections of 100,000 units of penicillin and systemic treatment with penicillin for three weeks. Treatment of the fourth patient with bilateral adnexitis and right pyosalpinx due to highly virulent streptococcus was a failure. The tumor disappeared after six local injections with 100,000 units of penicillin. Pyosalpinx developed at the left side and disappeared after three local injections of 100,000 units of penicillin, but new abscesses occurred which involved the entire small pelvis. Sulfonamide drugs, penicillin and streptomycin were ineffective, and death occurred after seven months of treatment. Local treatment with four to six injections of 100,000 to 300,000 units of penicillin every second day is recommended for pyosalpinx and acute and chronic parametritis, resulting in rapid recovery or modifying the patient's condition to such an extent that secondary surgical intervention may safely be carried out.

Biochemistry of Muscular Atrophy. J. C. Dreyfus and G. Schapira. —p. 1999.

*Study of Psychic Disturbances Associated with Tuberculous Meningitis Treated with Streptomycin. J. Scherrer.—p. 2004.

*Contribution to Study of Part Played by Microbes in Pathogenesis of Chronic Nephritis: Experimental Research on Permeability of Normal and Pathologic Kidney by Microbes. R. Carasso.—p. 2011.

**Psychic Disturbances Associated with Tuberculous Meningitis.**—Scherrer reports the occurrence of psychic disturbances in 21 of 30 patients with tuberculous meningitis in the first phase of the disease. The great majority of the patients were children and adolescents. Streptomycin therapy was instituted within one to ten days after the appearance of clinical signs of meningitis. The psychic disturbances consisted essentially of reduced consciousness reaching from a diminution of attention to stupor and to an anxiety state. The patients presented temporospatial disorientation, enuresis and occasionally hallucinations. The psychic disturbances were precocious and showed a tendency to regression on treatment with streptomycin. Dynamics of the cerebrospinal fluid may play a part in the pathogenesis of the mental confusion and amnesia seen in tuberculous meningitis.

**Microbes in Pathogenesis of Chronic Nephritis.**—Carasso made cytobacteriologic examinations of the urine of 34 patients with chronic nephritis and of 9 patients with ascending nephritis; i. e., chronic nephritis secondary to a prolonged infection of the pelvis of the kidney. In 29 of the 34 patients the urine was sterile and contained some leukocytes. In 6 of the 9 patients with ascending nephritis the urine contained abundant Bacillus coli and a large number of leukocytes. An emulsion of B. coli was injected into the marginal vein of the ear of adult healthy rabbits, and the urine and the blood of the animals were examined before and after the injection. The urine of the animals was sterile up to the seventh hour after the injection, and the culture of the urine was negative. A small number of bacilli were demonstrated in the urine after the seventh hour, and a large number appeared within the twenty-fourth to the forty-eighth hour. Decided albuminuria was manifested after the twenty-fourth hour of the inoculation. Characteristic lesions of acute glomeruloepithelial nephritis or of degenerative epithelial nephritis were revealed on microscopic examination of the kidneys. Blood culture from the rabbits was negative during the first hours of the inoculation; it became positive about the sixth hour, reaching its maximum at the twenty-fourth hour, and was negative again about the seventy-second hour. The bacilli probably pass out of the kidney by way of epithelial or glomeruloepithelial lesions. The microscopic picture of the lesions and the fact that bacillemia preceded bacilluria favor the hematogenic origin of this type of nephritis.

# Book Notices

**Textbook of the Nervous System: A Foundation for Clinical Neurology.** By H. Chandler Elliott, M.A., Ph.D., Assistant Professor of Anatomy, Medical College of the State of South Carolina, Charleston. With an introduction by Wilder Penfield, M.D. Fabrikoid. Price, $8. Pp. 384, with 158 illustrations and an atlas. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

This text concerns itself with descriptive anatomy of the human nervous system, neuroanatomy, and endeavors to present an integrated study of the nervous system by correlating structure with function. The author divides the text in two parts. Part I presents a brief and simple, yet complete, sketch of the nervous system. Part II, employing the sketch or framework of part I, adds details of structure and function which are necessary for a scientific knowledge of the nervous system.

The text is well illustrated by simple and understandable drawings which should appeal to the student and instructor alike. An adequate atlas of photographs with key drawings of representative levels of the nervous system is included at the end of the text.

The subject matter is up-to-date and cited references impress the reader that neurology is a relatively new science which is steadily progressing. This text, while primarily written for the medical student, should appeal to students who have less need for a detailed study of the human nervous system.

**Bacterial and Virus Diseases: Antisera, Toxoids, Vaccines and Tuberculins in Prophylaxis and Treatment.** By H. J. Parish, M.D., F.R.C.P.E., D.P.H., Clinical Research Director, Wellcome Foundation, Ltd. Cloth. Price, $2.75. Pp. 168, with illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

This pocket size book was written to present in convenient form the essential principles of immunology and their practical application in human medicine. The book is composed of sixteen chapters divided into three sections. The first section, entitled "General," is composed of four chapters. The second section, entitled "Antisera," is composed of five chapters which deal with the general properties of serums, antitoxic serums, antivenoms, antibacterial serum and antiviral serums. The third section is entitled "Serological Products for Active Immunization and Some Diagnostic Reagents," and is comprised of seven chapters dealing with immunization against diphtheria, scarlet fever, staphylococcus infections, tetanus and gas gangrene. One chapter is devoted to bacterial vaccines and one to tuberculins and BCG. vaccine. One chapter is concerned with active immunization against virus diseases. The final chapter is a tabulation of dates and discoveries with reference to specific diseases.

This book should prove valuable to the busy physician and to medical students. Obviously, with the discovery of the sulfonamide drugs and antibiotics, some of the work with antiserums and vaccines is rapidly becoming history.

**The Chemistry of the Carbon Compounds.** By Victor von Richter. Edited by the late Professor Richard Anschütz. Volume IV: The Heterocyclic Compounds. By F. Reindel (Translated by M. F. Darken), and Organic Free Radicals. By Ludwig Anschütz (Translated by A. J. Mee). Third English edition newly translated from the twelfth German edition. Cloth. Price, $12. Pp. 498. Elsevier Publishing Co., Inc., 215 Fourth Ave., New York 3, 1947.

This book, covering heterocyclic compounds and organic free radicals, is the last of the four volume series translated from the twelfth German edition. It is a concise and thorough text, covering the literature on these two topics through 1932. Delay in translation and publication due to the war accounts for the gap regarding recent literature.

**Youth in Despair.** By Ralph S. Banay. Cloth. Price, $3.50. Pp. 239. Coward-McCann, Inc., 2 W. 45th St., New York 19, 1948.

The former psychiatrist of Sing Sing gives an excellent review of all the legal, social and medical aspects of juvenile delinquency. He correlates all the findings of research; he examines carefully, with objectivity and understanding, the various factors which are considered as contributing to it, like the effects of war, poverty, broken homes, adverse parental and school influences, physical and mental diseases and handicaps. The discussion of all these factors is interspersed with illustrative case histories. The author concludes that the medical aspect, and particularly the psychologic and psychiatric dynamics of each child, are the most decisive factors leading to delinquency and must be primarily considered in prevention and treatment. The various methods to understand the individual delinquent are enumerated and evaluated, such as taking social history, the various psychologic tests and psychiatric interview; psychodrama and painting are included as methods of investigation and therapy.

The author examines critically the existing laws, agencies and institutions which deal with the problem, and finds them deplorably inadequate in every regard. He describes some well intentioned plans developed in the United States, England and Switzerland; but none is carried out to any extent. There is no coordinating over-all agency. Most detrimental of all, public opinion still adheres to a medieval notion that punishment is a means of prevention and correction, while actually it was proved a complete failure in both regards. Also the present trend toward slum clearance and extension of recreational facilities, desirable as it is, will not contribute much to the solution of the problem. It must be attacked at its core, which the author sees in the emotional and psychologic maladjustment of the child. Each child, not only the "problem child," should receive routine psychiatric-psychologic examinations, to the same extent as physical examination of school children is advocated.

In his distressing description of the inadequacies in contemporary efforts to deal with the problem of delinquency, the author does not realize one of the most distressing aspects. He advocates the establishment of child guidance clinics and extensive use of psychiatrists as an indispensable means to combat delinquency. But at the same time the author, who is psychoanalytically oriented, gives psychologic explanations which can hardly convince the public, the law makers and social institutions of the trustworthiness of psychiatric approaches. He considers delinquency "as compensative releases of unrequited sexual urges" (p. 103). He states that "the infant is all sex" (p. 102). The use of guns and knives is to the author a sign of obvious sexual aggression, because both are phallic symbols (p. 80). Such interpretations of dubious scientific validity are bound to defeat the author's plea for entrusting psychiatrists with the leadership in the fight against juvenile delinquency.

However, as a whole, the book is an excellent, clearly written and generally objective guide through the maze of conflicting reports and divergent recommendations on the subject.

**Eskimo Doctor.** By Aage Gilberg. Translated by Karin Elliott. Cloth Price, $3. Pp. 229, with photographs by the author. W. W. Norton & Co., Inc., 101 Fifth Ave., New York 3, 1948.

Prior to World War II, Greenland, the largest island in the world, was a Danish colony governed by the Royal Danish Trading Company in the interests of the Danish Crown Family. Its eastern, ice bound coast was practically uninhabited, while on the western shore as far north as Godhavn, on Disko Island, there were a number of provinces, each with a capital, governor, numerous artisans with their families and a contingent group of Eskimos, called in this book West Greenlanders, all of whom were in close contact with the Danish civilization in these outposts. Far to the north lived the Polar Eskimo in the region of Melville Bay, Cape York and Etah, until recent years without contact with or knowledge of the outside world, except for the brief visits of exploring expeditions. Access to Greenland was prohibited to all except those on company service, expeditions such as those of Commander MacMillan and Captain Bob Bartlet requiring permission obtained through the two departments of state.

Knud Rasmussen, son of a Danish governor and Eskimo mother, educated in Copenhagen as an ethnologist and anthropologist, totally ignored all regulations and established on Wolstenholm Sound, among the Polar Eskimos, a post named Thule which served successfully as a station for trading fur, ivory and Eskimo products, for a modest amount of enlightenment to the natives and as a base for his highly scientific Thule expeditions.

In this remote post, shortly after Rasmussen's death, a young Danish physician and his bride arrived to remain for a year. He, in his undergraduate days, had accompanied the Danish explorer Lauge Koch on two summer trips to the barren, uninhabited coast of Northeast Greenland, returning with great desire to visit the civilized west coast and to know the natives, particularly the Polar Eskimo.

The narration is a humorous, objective and realistic account of the character of these people, their social, domestic and economic problems, their maladies, superstitions, behavior under routine and critical circumstances, and their innate intelligence, this being entirely in accord with similar estimates by other of longer and more widespread experience.

His sledge trips by dog team in the long winter night to distant points are well told and without undue emphasis, and his portrayal of the Polar Eskimo as a jovial, fearless, kindly and friendly being explains his desire to return. The prevalent diseases, particularly those to which the Eskimos have acquired no racial or individual immunity, such as tuberculosis, with frequent meningitis, and the common childhood diseases of measles, whooping cough and scarlet fever, formerly unknown in the Far North, though prevalent in Southern Greenland as the result of frequent interchange of Danish residents, are at present treated at Thule, because of availability of sulphonamide drugs and other antibiotics, probably as effectively as in many areas in this country.

**Recent Advances in Obstetrics and Gynæcology.** By Aleck W. Bourne, M.A., M.B., B.Ch., *Obstetric Surgeon to St. Mary's Hospital, London* and Leslie H. Williams, M.D., M.S., F.R.C.S., Obstetric Surgeon to In-Patients, St. Mary's Hospital. Seventh edition. Fabrikoid. Price, $6. Pp. 326, with 85 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1948.

In the last twenty-two years, seven editions of this book have appeared. Ten chapters are devoted to obstetrics and six to gynecology. At the end of each chapter is a list of the references which are abstracted and discussed by the authors. The obstetric subjects chosen are: nutrition in pregnancy and fetal development, weight changes and water retention in pregnancy, the anaemias of pregnancy (by L. J. Davis), anesthesia and analgesia in obstetrics, penicillin in obstetrics, lactation, vitamin K and hemorrhagic disease of the newborn, erythroblastosis, stillbirth and neonatal death and radiology in obstetrics (by E. Rohan Williams).

The gynecologic subjects are: cancer of the cervix uteri, stress incontinence, sympathectomy, penicillin in gynecology, radiologic investigation and diagnosis in gynecology (by E. Rohan Williams) and roentgen therapy in gynecology (by W. M. Levitt). The authors not only have abstracted many articles dealing with these subjects but also have discussed the merits of the articles. They have accomplished their task admirably because the sixteen subjects are well chosen and thoroughly analyzed. The book should prove to be useful to all obstetricians and gynecologists.

**Atlas of Practical Incisions and Some Operative Procedures.** By Oliver C. Cox, M.D. Drawings by Garnet W. Jex; Photographs by John W. McGuire. Cloth. Price, $3. Pp. 85, with 61 plates. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

The author attempts to justify the small well placed incision in surgery. A number of photographs show the desired cosmetic effect and a few incisions are illustrated. Certainly, the cosmetic effect should be a secondary consideration. It does not seem possible to expose adequately the biliary ducts by the incision shown. A fine appendectomy scar is not necessarily the hallmark of surgical competency. This book adds little to medical literature except to show that a fine scar is attainable.

**Lehrbuch der Augenheilkunde.** Herausgegeben von M. Amsler, et al. Unter Mitarbeit von J. Babel, et al. Cloth. Price, 85 Swiss francs. Pp. 858, with 342 illustrations. S. Karger, Basel, Switzerland, 1948.

In the introduction to this large volume the authors give as the prime reason for this textbook in German by Swiss ophthalmologists the fact that because of the second World War, such an up-to-date text could not be published by German authorities. Many of these same Swiss ophthalmologists have published much in the literature. Brückner, Amsler and Vogt, now deceased, have written textbooks. Vogt's work with the slitlamp while head of the department at the University of Zurich is basic and world renowned.

The textbook follows the usual pattern with chapters on methods of examination, diseases of the various ocular tissues, anamolies, injuries, etc.

Many of the illustrations are of outmoded instruments; others are foreign to English-speaking ophthalmologists. The illustrations of anatomy and optic pathways are unusually fine. The index is good but there is no reference index. The authors should be given an E for effort in publishing this book during such trying times, but in general it is not up to the standard of previous textbooks in German. Undoubtedly improvement will be made if a second edition is forthcoming.

**L'oeuvre scientifique de Fr. J. Rainer.** I: Neurologie végétative. II. Structure fonctionnelle. III. Anthropologie, morphologie (varia), bibliographie. Paper. Pp. 57; 154; 121, with 75; 115; 105 illustrations. Monitorul oficial şi Imprimeriile Statului, Imprimeria natională, Bucharest, 1945.

These three volumes represent the collected publications of the author published posthumously by the Romanian Academy in French. Volume I contains papers on the autonomic nervous system, including the thoracic sympathetic nerves, cardiac nerves, nervi erigentes and innervation of the arteries. Plates illustrating cardiac nerves and the sympathetic and parasympathetic nerves of the neck and chest are excellent. Volume II relates to functional morphology of structures including the dura mater, periosteum, face, pelvis, vertebral column, pericardium and pacinian corpuscle. Volume III is a miscellaneous assortment. Papers dealing with variations in the hepatic fissures, genesis and structure of elastic fibers, variations in the coracobrachialis and biceps brachii muscles, innervation of the abdominal wall and the lymphatic system of the heart are included. Plates of lymphatic vessels of the heart are noteworthy.

Anatomists and others interested in special topics treated in these works will find them useful.

**Nouveaux traitements de l'insuffisance hépatique.** Par Jean Cottet et Nicolas Dobo. Préface de M. le Professor E. Chabrol. Paper. Price, 375 francs. Pp. 210. Editions médicales Flammarion, 22 rue du Vaugirard, Paris, 6^e^, 1948.

This book reviews the present knowledge and current hypotheses governing the treatment ,and prevention of hepatic disease and hepatic failure. After a short historical review, the rationale, indications and contraindications and methods of the different forms of treatment of hepatic insufficiency are discussed. This includes high carbohydrate diet with and without injections of insulin, administration of liver extracts, bile salt therapy, administration of sulfur (especially in the form of glutathione and methionine), and the use of the various vitamins and hormones. Another part deals with the physiopathologic basis and the practical use of the therapy with the different lipotropic substances and of the oral and parenteral high protein regimen. Special emphasis is given to therapeutic results in cirrhosis. The available literature is well and critically reviewed and an extensive bibliography makes the booklet valuable to the American reader. Many of the facts presented and the conclusions reached are based on American and also on British or German investigations.

**Pye's Surgical Handicraft: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of Surgical Dressers, House Surgeons, and Practitioners.** Edited by Hamilton Bailey, F.R.C.S. Eng., Surgeon, Royal Northern Hospital, London. Fifteenth edition. Cloth. Price, $7. Pp. 668, with 789 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This book attempts to educate house surgeons on practical technics in the hospital. It does not compare with similar books issued in this country. Some of the methods are primitive. The book is of little value for American interns or residents.

**Food, Nutrition and Health.** By E. V. McCollum, Ph.D., Sc.D., and J. Ernestine Becker, M.A. Sixth edition. Cloth. Price, $2. Pp. 146. The Authors, Gilman Hall, Johns Hopkins University, Baltimore 18, 1947.

This book presents the basic knowledge of nutrition in a concise simple manner. It is written for the public and may be recommended to the intelligent layman who desires to procure a sound foundation in food values and nutritional principles.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## SKIN TEST TECHNIC

**To the Editor:—I usually inject tetanus antitoxin for passive protection in two doses, 3 minims at once and the rest after half hour if there is no reaction. Is this method sufficient to prevent anaphylactic reaction? If not, how should the skin test be performed?**
**M.D., Illinois.**

ANSWER.—The following outline describes the cutaneous tests employed to determine the presence or absence of sensitivity to the serum employed; in the case of tetanus, usually horse serum.

*Cutaneous Tests*

| Technic | Remarks |
|---|---|
| A. Scratch test<br>1. Make 2 superficial scratches on front (volar) surface of either forearm<br>2. Apply a drop of 1:10 dilution (0.1 cc. serum in 9.9 cc. of isotonic NaCl solution) over upper scratch (use lower scratch as control)<br>3. If, after 15 to 20 minutes, no local or constitutional reaction occurs, proceed to the intracutaneous test, described under (4)<br>B. Intracutaneous test<br>4. Raise a tiny wheal (smallest amount of serum practicable) on the front (volar) aspect of either forearm<br>5. Use the following dilutions:<br>Presumptive positive sensitivity*: 1:10,000 dilution<br>Negative sensitivity*: 1:1,000 dilution<br>Under all circumstances: at 15 to 20 minute intervals, if preceding dilutions give negative readings, repeat tests in the order of the *next lower dilution: 1:1,000,* 1:100, 1:10 | 1. Positive local reaction: area of edema about 0.5 inch in diameter with erythema (like a wheal), with or without finger-like projections at circumference (pseudopodia); appears within 15 to 20 minutes<br>2. A negative reaction does not always *mean that it is safe to give serum*<br>3. A positive reaction does not always indicate that it is dangerous to give serum<br>4. But, when a positive reaction does prove to indicate clinical sensitivity, the sooner the reaction, and the greater its size, the greater is the likelihood of a constitutional (anaphylactic) reaction<br>5. The tests must be given each time serum is to be injected (may change from positive to negative or vice versa)<br>6. Constitutional reactions (various forms of "serum sickness") to skin tests are identical with those which follow injections of serum for prophylaxis or therapy; they may follow with either negative or positive skin reactions |

* *Presumptive diagnosis of serum sensitivity:* (*a*) presence of allergic complaints (hay fever, asthma, hives, food sensitivities, migraine, eczema, etc.) in the patient or relatives (past or present); (*b*) serum injections in the past (tetanus, diphtheria, pneumonia, etc.), without any reaction (early or late). Probable sensitivity: (*a*) skin reactions (or ophthalmic reactions) positive on previous occasions; (*b*) allergic complaints (sneezing, coughing, wheezing, burning eyes, stomach ache, hives, itching, headache, etc.) when around horses (if *horse serum is to be used*) or cows (if bovine serum is to be used). Positive sensitivity: (*a*) allergic difficulties from previous injections of horse serum; (*b*) constitutional (anaphylactic) reaction from cutaneous or ophthalmic tests for sensitivity; (*c*) constitutional reaction during present injections.

The following outline should be helpful in avoiding mild to fatal reactions to prophylactic and therapeutic doses of antitetanic serum:

1. Administer tetanus antitoxin only if essential.
   - (*a*) Are the indications present? Can care of the local lesion by itself be adequate?
   - (*b*) Can tetanus toxoid be used in place of tetanus antitoxin? A booster dose of 0.1 cc. of either fluid or alum-precipitated toxoid is adequate even though tetanus toxoid was injected five to six years previously. In certain instances (delay, strong local lesions, hemorrhage) a booster dose of tetanus toxoid should be supplemented with 10,000 units of tetanus antitoxin.
2. Determine whether the patient is sensitive to horse serum (history, physical examination, skin tests: already presented in the preceding paragraphs).
3. Under all circumstances, adopt the following measures to avoid reactions to tetanus antitoxin:
   - (*a*) Administer an appropriate antihistamine compound, in sufficient quantity, orally or parenterally (when feasible), at least thirty minutes before injecting tetanus antitoxin (no matter what the history, physical examination or tests reveal).
   - (*b*) A syringe containing 2 cc. of epinephrine hydrochloride (1:1,000) should be immediately available to treat any acute serum reactions.
   - (*c*) A syringe containing 5 cc. of diphenhydramine hydrochloride (for intravenous injection) should be immediately available to assist in the control of acute serum reactions (1 to 2 cc. to be injected, and repeated as necessary).
   - (*d*) In the presence of a probable or positive diagnosis of serum sensitivity, the patient should be hospitalized for at least twenty-four to forty-eight hours.
   - (*e*) All patients who receive tetanus antitoxin (independent of history, physical examination or tests) should be given one of the antihistamine compounds for fourteen days to avoid all forms of serum sickness.
   - (*f*) In the presence of a presumptive, probable, or positive diagnosis of serum sensitivity, in addition to antihistamine therapy, hospitalization and epinephrine hydrochloride (as needed), employ the following method of hyposensitization:

| Dilution of Antitoxin | Volume | Route | Interval and Remarks |
|---|---|---|---|
| 1:1,000 | 0.1<br>0.2<br>0.3<br>0.5<br>1.0 | Subcutaneous | *15 minutes* between each injection of antitoxin |
| 1:100 | 0.1<br>0.2<br>0.5<br>1.0 | Subcutaneous | In case of reactions during course of injections, treat reactions, continue dose preceding reaction, gradually increase dose if further difficulty is not encountered |
| *1:10* | 0.1<br>0.2<br>0.5<br>1.0 | Subcutaneous | In case of reactions, increase intervals between injections to 30 minutes |
| None (undiluted) | 0.1<br>0.2<br>0.5<br>1.0<br>Rest of serum as one dose intramuscularly | Subcutaneous | |

   - (*g*) At an appropriate interval after serum prophylaxis (four to six weeks after the now recommended dose of 5,000 to 10,000 units) inject 0.5 cc. of alum-precipitated tetanus toxoid (use the newly marked purified products) and repeat dose in one month. Thus, *on subsequent occasions, tetanus toxoid may* be employed in the form of booster doses in place of antitetanic serum.

## TUBERCULOSIS AND COCCIDIOIDOMYCOSIS

**To the Editor:—Does a person who has recovered from severe pulmonary tuberculosis have increased susceptibility to pulmonary forms of coccidioidomycosis or histoplasmosis? May susceptibility be increased because of scarring from the tuberculosis? Are any parts of the United States free from these infections or are known endemic areas localized?**
**D. M. Nelson, M.D., Detroit.**

ANSWER.—Persons who have recovered from severe pulmonary tuberculosis have not been shown to have increased susceptibility to coccidioidomycosis or histoplasmosis. Occasionally after tuberculosis a residual bronchiectasis occurs, but this of itself should not predispose to these other specific infections.

Coccidioidomycosis has been found in practically every part of the United States in persons who have not left these areas. There are certain parts of the country where the disease has a high incidence; namely, the desert regions of the West and the valley regions of California. The infection is common in these areas and rare in other parts of the country.

## PREPARATION OF SKELETON

**To the Editor:—How can I bleach and dry the bones of a human skeleton?**
**Richard C. Batt, M.D., Glens Falls, New York.**

ANSWER.—Since the query refers merely to bleaching and drying of bones in the preparation of a human skeleton, nothing will be said here about the maceration, cleaning and degreasing of bones.

If carbon tetrachloride has been used in the degreasing process, the bones must be thoroughly dry before bleaching. Dry not too rapidly (for bones will crack—long bones, lengthwise—if oven or hot sun is used in drying). Then place the dry bones in hydrogen peroxide and water (2 or 3 parts of water and 1 part of hydrogen peroxide) for bleaching. The length of time required for this process will vary (hours or days), depending on the thickness or character of the bones and the potency of the hydrogen peroxide. When the bones have attained the desired whiteness, dry them (again not too rapidly).

## SPONTANEOUS PNEUMOTHORAX

*To the Editor:*—A man, aged 30, has recently had his sixth spontaneous pneumothorax in two years. Three have involved the right side and three the left side. On the last occasion a partial collapse of the upper lobe of the left lung was demonstrated by roentgen examination of the chest. Evidence of active or healed tuberculosis was absent. Except for the aforesaid finding physical examination did not reveal any significant abnormality. Complete blood counts, serologic reactions, sedimentation rate and urine were normal. The patient's brother has had advanced pulmonary tuberculosis, but he has not had contact with his brother in the last ten years. The patient's occupation requires moderately strenuous exertion, but several of the attacks have occurred at rest. Symptoms consist of a moderately severe dull aching pain (described as similar to "indigestion") and slight dyspnea. Each attack necessitates several weeks of convalescence, and the patient is anxious that something be done in an effort to prevent recurrences. I have considered two courses of action: (1) a course of treatment with streptomycin, chiefly because of the positive family history and the fact that in a certain proportion of such cases clinical tuberculosis eventually develops; (2) injection of an irritating substance into the pleural space in an effort to produce an adhesive pleuritis. Would a concentrated solution of penicillin produce such an effect? This second method seems too drastic to me. I would appreciate advice concerning the handling of this patient.

Ben F. Roach, M.D., Lexington, Ky.

Answer.—Spontaneous collapse of a lung is a rather unusual event, rarely happening more than once in the same person, and in most cases is the result of rupture of a subpleural bleb or cyst. Repeated spontaneous collapse of one or both lungs may occur with sufficient frequency to warrant some type of therapy designed to obliterate the pleural space, thereby preventing further recurrence of the difficulty. Should spontaneous pneumothorax be due to tuberculosis, however, specific therapy for the underlying pathologic condition should be obtained. In order to rule out active tuberculosis in a patient with spontaneous pneumothorax, roentgenograms of the chest should be taken before and during reexpansion of the lung in an effort to demonstrate abnormal shadows. Repeatedly negative roentgenograms and/or several successive negative guinea pig inoculations with gastric samples should adequately rule out the presence of an active tuberculous focus. If the disease has been excluded at the time, the patient is no likelier to contract tuberculosis later than the average patient. (Cohen, S., and Kinsman, J. M.: Nontraumatic Spontaneous Pneumothorax Among Military Personnel, *New England J. Med.* 235:461 [Sept. 26] 1946). Because of the toxic properties of streptomycin and the easily developed resistance to the drug, even a prophylactic course of this medication would be definitely contraindicated in the case cited. After tuberculosis has been ruled out in a case of repeated, incapacitating spontaneous pneumothorax, as in the patient mentioned, production of an adhesive pleuritis to obliterate the pleural space is probably indicated. John D. Steele (*Am. Rev. Tuberc.* 56:299 [Oct.] 1947) recommended insufflation of 8 to 10 Gm. of sterile talc through a thoracoscope as the most successful means of obtaining satisfactory results. Other methods of producing adhesive pleuritis have not yielded such uniformly good pleural symphysis.

## PNEUMATIC TOURNIQUET

*To the Editor:*—What is the accepted method of using a pneumatic tourniquet to produce a bloodless field in surgery of the extremities? What is the proper inflation pressure and how long can the tourniquet be safely applied?

M.D., New York.

Answer.—A pneumatic tourniquet creates a wide even pressure and is quickly inflated and deflated. It may be operated by a hand or foot pump. For the upper extremity an ordinary blood pressure cuff is sufficient with pressures well above the systolic blood pressure of the patient. For the lower extremity, the Bird-Campbell tourniquet is useful and is inflated to 15 pounds of pressure. It is wise to deflate the cuff every thirty to forty-five minutes to avoid ischemic neuropathy of the peripheral nerves. The tourniquets are obtainable through larger instrument dealers.

## INFORMING THE PATIENT WITH CANCER

*To the Editor:*—In view of the present trend toward making the public "cancer conscious," what should the physician's feeling be in regard to revealing a diagnosis of cancer to the patient? Will not a more enlightened patient be better able to cooperate with the physician if he is told the true state of affairs?

Russell E. Schlitter, M.D., Highwood, Ill.

Answer.—There can be no question about the vital advantage to the patient with cancer of cooperating intelligently with his physician. To do so, the patient must understand the situation. Consequently, whenever it is possible without disadvantage to the patient the diagnosis of cancer should be discussed with him as tactfully and optimistically as possible. If exact information has to be withheld for some special reason, the physician should establish confidential relations with some suitable member of the patient's family.

## TUBERCULIN PATCH TESTS

*To the Editor:*—Of what significance is a positive reaction to a patch test for tuberculosis in an adult?

M.D., New York.

Answer.—A reaction to the patch tuberculin test in an adult has the same significance as a reaction to the epidermal (Pirquet), the intracutaneous (Mantoux) or any other method of administering the tuberculin test. A tuberculin reaction in an adult has the same significance as in a child; namely, that at least primary lesions are present and that they probably contain living tubercle bacilli. If a reaction occurs the first time that an adult is tested one is unable to determine how long the primary lesions (tuberculous infection) have been present. Many adults now receive tuberculin tests periodically as long as there is no reaction. If a reaction occurs in a person who, six months or a year before, was a nonreactor, one is certain that there has been an effective contact with a contagious case of tuberculosis in the interim. This is as significant as when a child of 6 months to 1 year is found to be a reactor from the standpoint of dating the exposure and the duration of the disease.

After tubercle bacilli first invade the body there is an interval of three to seven weeks before the tissues are so sensitized that a reaction is elicited by the patch or any other method of administering tuberculin. This is the preallergic stage of the disease. When allergy first appears it soon reaches such a high level as to be detectable by an exceedingly small amount of tuberculin. However, if no exogenous or endogenous reinfection occurs it wanes until it can be elicited only by larger doses of tuberculin such as 1 mg. In some cases it even sinks below this level, and if all the tubercle bacilli die in the body, which probably happens more frequently than was formerly believed, allergy completely disappears, so that there is no response to 5 or even 10 mg. of tuberculin.

The adult who reacts even mildly to the patch test still has a reasonably high degree of allergy. When an intense reaction follows the administration of the patch test it probably means that the primary disease developed relatively recently or that the person is being reinfected endogenously or exogenously.

Inasmuch as only living tubercle bacilli result in allergy elicited by the tuberculin test and since only in persons whose bodies contain tubercle bacilli does clinical tuberculosis develop, it is exceedingly important that every adult reactor to the patch or any other method of administering tuberculin be examined at once to determine whether lesions have become so gross that their locations can be detected by such procedures as roentgen inspection of the chest; if none is found the person should be reexamined periodically, as such lesions may be in evidence at any subsequent time as long as the allergy persists. The old belief, once a reactor, always a reactor, must be abandoned in the light of present evidence. Therefore the adult who reacts to tuberculin should have the test repeated every three to five years to determine whether the sensitivity is waning or has completely disappeared.

The rapidity with which tubercle bacilli die in human bodies varies greatly. In some apparently only a few years are required; in others, much longer, and in a considerable number the organisms live and retain their virulence over decades or the entire lifetime.

It is not known how long allergy lingers after all tubercle bacilli die in a human body. Some believe it is only a month or so, while others think that it may persist up to two years. In any event, there is no way to determine from the tuberculin reaction during this short period that all bacilli have died. Therefore, the safe course is to regard a tuberculin reaction as indicative of the presence of living tubercle bacilli.

There is still a belief that all adults have primary tuberculosis (tuberculous infection) and therefore would react to tuberculin. While this may have been true here a few decades ago and still is in some parts of the world, such a belief is now obsolete in most parts of the United States. Controlling tuberculosis in domestic animals, isolating large numbers of contagious cases in man in hospitals and sanatoriums and adequate treatment of many others have protected large numbers of children and adults from becoming infected. These, together with those in whom infections die, constitute the majority of adults in many places. Jordan reported the tuberculin testing of nearly 3,698 adults ranging from 21 to 71 years, of whom only 21.6 per cent reacted to tuberculin. Therefore it is as important to test adults as children, and the significance of the reaction is the same in adulthood as in childhood.

## "LIPAN"

*To the Editor:*—Please furnish information about "lipan" in treatment of psoriasis.

W. W. Sherwood, M.D., Los Angeles.

Answer.—"Lipan," according to the labeling, is a tablet containing undeclared amounts of powdered pancreas, vitamin $B_1$, vitamin D and sodium bicarbonate. Its use in psoriasis is based on the doubtful theory that this disease is due to a defect in lipid metabolism. Presumably the powdered pancreas furnishes a source of lipase.

As pointed out by Beckman (Treatment in General Practice, Philadelphia, W. B. Saunders Company, 1945) psoriasis "will respond at times to almost anything or again to nothing at all." Madden (J. A. M. A. **115**:588, 1940) who treated 112 patients with a large variety of agents, including vitamins D and $B_1$ did not observe impressive results. Schonberg (*Ohio State M. J.* **42**:254 [March] 1946) stated that the various types of parenteral and enteral medication employed in his series of 207 cases were not of apparent value.

Promoters of "lipan" stress its value in correcting faulty fat metabolism. They refer to the work of Dragstedt with lipocaic, a similar substance. The report of the Council on Pharmacy and Chemistry, "The Present Status of Lipocaic" (J. A. M. A. **115**:1454 [Oct. 26] 1940), asserted that conclusive evidence of the value of lipocaic in psoriasis is lacking. This view remains unaltered.

Competent dermatologists who have thoroughly investigated the relation of fat metabolism to psoriasis conclude that such relationship does not exist. "Lipan" is apparently offered on the basis of an untenable theory.

## PTEROYLTRIGLUTAMIC ACID

*To the Editor:*—Please give information on the use of "teropterin" (pteroyltriglutamic acid) in cancers involving the esophagus.

M. A. Johnson, M.D., Plainview, Neb.

Answer.—"Teropterin" (pteroyltriglutamic acid) is a folic acid derivative and has been found to inhibit and cause regression of spontaneous cancers of the breast in mice. The effectiveness of the drug on carcinoma of the esophagus, or of other parts of the human body, is questionable. Conclusive evidence has not yet developed that it is effective in the treatment of carcinoma. Pteroyltriglutamic acid may reduce pain and improve the sense of well-being in cases of esophageal carcinoma, but it cannot be used as a substitute for the usual methods of treatment; i. e., surgical extirpation, maintenance of nutrition, radiation therapy and measures contributing to comfort. At present experience with the drug is too limited to indicate definitely that it will be a valuable adjunct in the treatment of carcinoma. Dosage has been from 20 to 50 mg. a day, administered intramuscularly. No local or systemic reactions have been observed.

Attention is called to the Report of the Council on Pharmacy and Chemistry (J. A. M. A. **137**:699 [June 19] 1948), which, on the basis of the available evidence, concluded that beneficial effects from "teropterin" therapy of cancer had not been demonstrated.

## FETAL INJURY

*To the Editor:*—Is there a danger of an infant's being born deformed or injured physically or mentally if an unsuccessful attempt was made at termination of the conception?

M.D., Wisconsin.

Answer.—The question is not clear. If by "termination of the conception" is meant the end of pregnancy then unsuccessful attempts to start labor cannot produce deformity of the baby. Likewise, unless there is direct injury to the baby's head by some mechanical means there will be no effects on the brain to produce mental disturbances.

If the query implies an unsuccessful attempt to empty the uterus immediately after conception takes place in order to produce an abortion, there is a possibility that harm may result in the fetus. Since coitus and fertilization occur within twenty-four hours, a curettement a day or two after this will secure only endomentrium and not decidua and certainly not products of conception. If there is no endometrial lining left to form decidua, it is almost certain that the fertilized ovum will not implant itself in the uterus but will perish. If there is some small amount of endometrium left in the uterus and it is defective for one reason or another and the ovum is implanted on this, the developing ovum can become abnormal because of faulty environment.

## COTTON THREAD SUTURES

*To the Editor:*—Can ordinary thread as it is bought in 5 and 10 cent stores (cotton) be used for minor operations?

M.D., Tennessee.

Answer.—Ordinary cotton or silk thread such as is purchased in a dry goods store can be satisfactorily used for major or minor surgical operations. This thread can be sterilized and, except for some minor properties, is just as satisfactory as that supplied by the surgical supply houses.

## SYPHILIS

*To the Editor:*—In the Journal, August 21, page 1567, appears a query regarding management of a young man and a young woman, both of whom presumably have syphilis, with an answer to which I take issue.

On the basis of the inadequate information supplied, it is probable that the young man does have syphilis, although the duration of his infection cannot be determined from the information given. The reply correctly enquires whether this patient presents any physical evidence suggestive of syphilis and implies, although it does not definitely say so, that, if such physical evidence is present, further treatment may be desirable depending on the type of clinical abnormality. To this reply should be added the statement that further treatment, if any, cannot be planned without knowledge as to the patient's physical status. The reply also correctly suggests that the spinal fluid should be examined (including a Wassermann test). To this should be added that the spinal fluid examination should also include a cell count, quantitative protein determination, quantitatively titered complement fixation (not flocculation) test, and a colloidal test. The reply does not state what should be done if the spinal fluid is now normal. Should this prove to be the case and should the patient have no physical evidence of syphilis, he has now had enough treatment and none further need be given, regardless of the fact that he still has a "strongly positive" blood reaction.

The reply further indicates that if the spinal fluid is "positive," the patient should be given fever treatment and "simultaneous intravenous penicillin." This is definitely erroneous information. Whether fever treatment is necessary depends not only on whether the spinal fluid is "positive" but on the general pattern of spinal fluid abnormalities, if any are present. If the spinal fluid shows maximal abnormalities of the type usually associated with dementia paralytica (the so-called paretic formula), fever treatment *may* be desirable. If the spinal fluid abnormalities are less in degree than this, fever treatment is almost certainly unnecessary and penicillin, intramuscularly administered, total dose 10,000,000 to 20,000,000 units, is almost certainly entirely adequate. The intravenous use of penicillin in the treatment of syphilis has long since been abandoned.

As to the young woman in question, there is substantial doubt as to whether she has syphilis and, if so, whether she acquired it from the young man. The enquirer apparently treated this young woman on the sole ground that she had become pregnant by a man who had syphilis and was without any evidence of syphilis herself, since no data are given as to her examinations, clinical or laboratory, before treatment was administered to her. The fact that she has after treatment a "slightly positive" blood reaction suggests that she may have had a syphilitic infection, but, as the reply properly indicates, does not verify the fact, since she may have a biologic false positive serologic reaction. Nevertheless, her spinal fluid also should be examined although not until after delivery. No further treatment is necessary during her pregnancy and, if her spinal fluid and physical condition are normal, no further treatment need be given after delivery.

Assuming in each case physical normality and normal spinal fluids, both the male and female patient should be followed indefinitely in the manner frequently publicized for the followup of patients with early syphilis, most recently in the Report of the Syphilis Study Section to the Council on Pharmacy and Chemistry, "Penicillin in the Treatment of Syphilis," The Journal, March 27, page 873.

In all probability, the enquirer has gained nothing by giving the patients neoarsphenamine and bismuth in addition to 3,000,000 units of penicillin.

The reply states that the infant should be followed with a serologic test on the cord blood and "a monthly blood test" but does not indicate for how long this should be continued. This question is also discussed in the report of the Syphilis Study Section already referred to.

The enquirer states, "By law in Ohio they [this couple] are denied a marriage license." The reply suggests that after the enquirer has carried out all of the suggestions made in the reply, the marriage certificate might be issued. In many states, presumably including Ohio, a positive blood reaction in one or both applicants for marriage is not a bar to marriage unless the applicant is infectious. When both applicants for a marriage license have syphilis, it would be a reductio ad absurdum to withhold a marriage license. No pre-marital blood testing law adopted in any state is designed to prevent the marriage of a person who has syphilis but instead only to minimize the spread of syphilis in marriage. Almost certainly this young couple could have been married with medical and legal consent at any time they wished and there is absolutely no reason to defer marriage now. On the contrary, and for the sake of legitimization of the child, and assuming of course that the couple wish to marry, they may do so at once.

Finally, the reply to this enquiry contains the suggestion that treatment given to the girl should be modified if the man has a positive spinal fluid reaction. This is the first time, to my knowledge, that it has been proposed that one patient be treated in a certain manner because a different patient had something the matter with him. It should seem obvious that the treatment given to the girl depends on what the matter is with the girl, not on what the matter is with the man.

## DIAGNOSIS OF GASTRIC NEOPLASMS

### By Cytologic Examination of Gastric Secretions

H. MARVIN POLLARD, M.D.

WINSTON C. HALL, M.D.
Ann Arbor, Mich.

The high incidence of gastric carcinoma together with its extremely low survival rate[1] provides adequate justification for the search and evaluation of new methods of diagnosis. This is particularly rational in view of the often repeated opinion that improvement in the end result of gastric carcinoma can be expected only from earlier diagnosis of the lesions.[2]

In 1946 Papanicolaou[3] reported on the diagnostic value of exfoliated cells from cancerous tissues. Although the technic which he discussed was applied largely to the diagnosis of neoplasms in the female genital tract, it was also utilized as an aid in the diagnosis of neoplasms of other systems, including the stomach. Since this early report the same observer has reported more extensive experiences in the diagnosis of gastric neoplasms by the examination of cells from the gastric juice.[4]

His results compared well with those of sputum and urine except for a somewhat higher percentage of false negative results. The increased number of false negative results was attributed to (1) rapid deterioration of cells in the gastric fluid unless the specimen was fixed immediately, (2) the absence of exfoliation in the relatively large group of scirrhous carcinomas which as a rule do not reach the mucosal surface and (3) the frequent presence of swallowed foreign cells from nasal, pharyngeal, tracheal and esophageal mucosae and of undigested foreign particles. These foreign elements tend to confuse the picture and to make the recognition of neoplastic cells more difficult.

Hunter and Richardson[5] modified the Papanicolaou procedure in that embedding and sectioning of the sediment from gastric juice were employed instead of the usual procedure of smearing the sediment. They claimed better results with this procedure, but offered no statistical data in regard to their results. More recently Meigs and his co-workers[6] reported their results employing the procedure of Papanicolaou. Of the 50 cases in which gastric aspiration was carried out, neoplasms were proved to be present in 24. The smear was positive for neoplastic cells in 15 instances. In 1 case there was a false positive result, since no neoplasm was found at operation, while in 2 other instances with positive smears no neoplasm was found grossly, but histologic examination revealed preinvasive carcinoma. These authors emphasized the value of the Papanicolaou procedure in detecting early gastric neoplasms.

Since July 1947, we have employed the Papanicolaou procedure in the study of gastric sediment. The microscopic examinations of the cells contained in the fasting gastric contents of 278 patients were carried out in an effort to evaluate this technic as an aid in the diagnosis of gastric carcinoma. In some cases more than one aspiration was performed on a single patient, so that altogether 326 aspirations were done. The group of patients studied were selected, in view of the fact that they all had gastrointestinal complaints. No attempt was made to use the technic as a screening or survey procedure. As nearly as possible, the technic advised by Papanicolaou[4a] was used throughout. After an overnight fast, the gastric contents were aspirated through a Levine tube, and to this material an equal volume of 95 per cent alcohol was added immediately. After centrifugation, the clear layer was discarded and the sediment was smeared and fixed. The slides were run through the usual solutions, strained and prepared for microscopic examination. This procedure was finally followed in the vast majority of the cases. This technic was compared to the results in which aspiration was carried out after alcohol or histamine stimulation of gastric juice. In some instances the stomach was washed out with 5 per cent sodium bicarbonate. We found little difference in either the preservation of gastric cells or their straining qualities.

All slides were studied by the same pathologist, one of us (H. C. B.), who found that, while some positive slides can be evaluated quickly, approximately twenty minutes are necessary before a negative preparation can be safely discarded. In some cases suspicious, but

nonspecific, cellular changes make an absolute diagnosis by this method impossible, despite an infinitely prolonged period of study. The pathologist has repeatedly emphasized the fact that there is no single criterion of malignancy in the individual cell which may not occur in a normal cell and that the most dependable sign of malignancy, invasion of surrounding tissue, is not available in this type of examination.

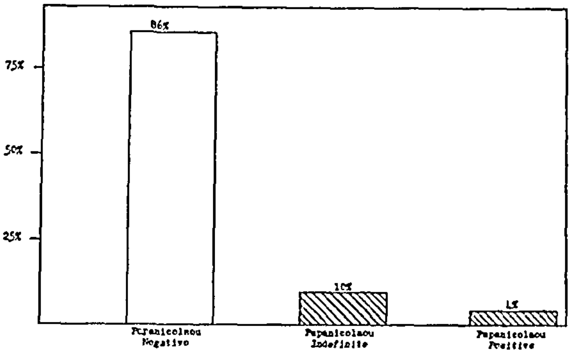

Fig. 1.—Results of cytologic study of gastric juice from patients in whom there was no clinical evidence of carcinoma of the stomach (one hundred and ninety-two aspirations).

Our effort to evaluate the procedure has consisted of comparing the diagnosis made by the microscopic study of the cells structure of the gastric juice with the clinical diagnosis. The clinical diagnosis is based on a thorough study of each case by the usual applicable methods, including the history, physical examination, roentgenography, gastroscopy and histologic study of material obtained at laparotomy or biopsy. This series includes only those cases in which it is felt that a final diagnosis has been established. Of the three hundred and twenty-six smears examined, only two hundred and ninety-six were satisfactory. In the other thirty, there was so much foreign material or the cells were in such a poor state of preparation that the histologic evaluation of the cells was impossible. The remaining material (two hundred and ninety-six smears) can be divided into four general categories.

## GENERAL CATEGORIES

*Group I: Clinically No Neoplasm.*—The first group consists of one hundred and ninety-two aspirations in which full clinical evaluation disclosed no evidence of carcinoma of the stomach. In this group 86 per cent of the aspirations were thought to contain no malignant cells. In 10 per cent the results of the cytologic examinations were indefinite, while 4 per cent were falsely reported as positive for carcinoma (fig. 1).

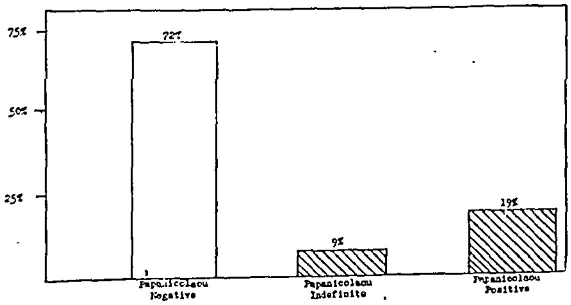

Fig. 2.—Results in patients with no histologic evidence of carcinoma of the stomach (forty-three aspirations).

*Group II: No Histologic Evidence of Neoplasm.*—A second, and possibly more reliable group, is furnished by the fact that forty-three gastric samples were obtained from patients who were subsequently subjected to laparotomy (fig. 2).

In all of these cases, examination in the Pathology Department of part or all of the stomach revealed no evidence of carcinoma. While it is possible that lesions not evident grossly may have been missed, this is not likely in a significant number. In this group, microscopic study of the fasting gastric contents revealed only normal cells in 72 per cent. No definite conclusion could be drawn in 9 per cent of the aspirations, while in 19 per cent of the slides studied it was felt that malignant cells were identified.

*Group III: Clinically Neoplasm.*—Twenty gastric aspirations were done on patients in whom a final diagnosis of gastric carcinoma was made, in which no histologic confirmation of the diagnosis was obtained (fig. 3). Despite the clinical picture, no malignant cells were found in the fasting gastric contents in 12 (60 per cent) of these cases, while a positive report was made in only 8 (40 per cent).

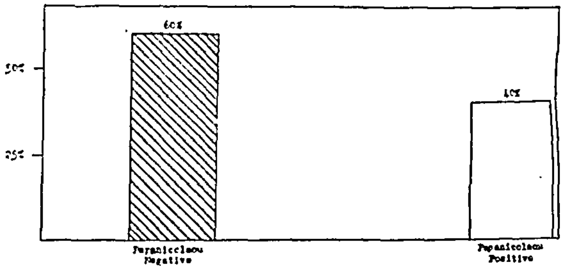

Fig. 3.—Results in patients with a clinical diagnosis of carcinoma of the stomach without histologic confirmation (twenty aspirations).

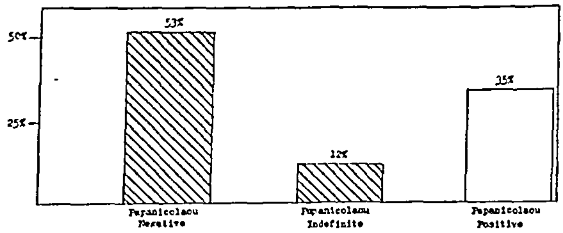

Fig. 4.—Results in patients with histologic diagnosis of carcinoma of the stomach (forty-one aspirations).

*Group IV: Histologically Neoplasm.*—We had an opportunity on forty-one occasions to examine the cell structure of the fasting gastric contents of patients who were later proved to have gastric carcinoma by laparotomy (fig. 4). No recognized malignant cells were encountered in 22 cases (53 per cent). Malignant cells were found in 14 cases (35 per cent), while in 5 cases (12 per cent) no definite conclusion could be reached.

By ignoring the previously considered clinical groups and tabulating the results of all gastric aspirations, one can gain a more complete picture of the results (fig. 5). We found that in 59 per cent of all the aspirations studied and reported as positive, the cytologic observations were confirmed by clinical and conventional histologic study. On the other hand, when the aspirations were reported as negative, results in 85 per cent of them coincided with the results in other studies.

In all those cases in which a final diagnosis of carcinoma of the stomach was made, the result in the aspiration technic was correct in 36 per cent (fig. 6). This may be said to represent the sensitivity of the procedure. In contrast, specificity is reflected by the fact that in all those cases in which no carcinoma was found, the result of the gastric aspiration technic was correct in 87 per cent.

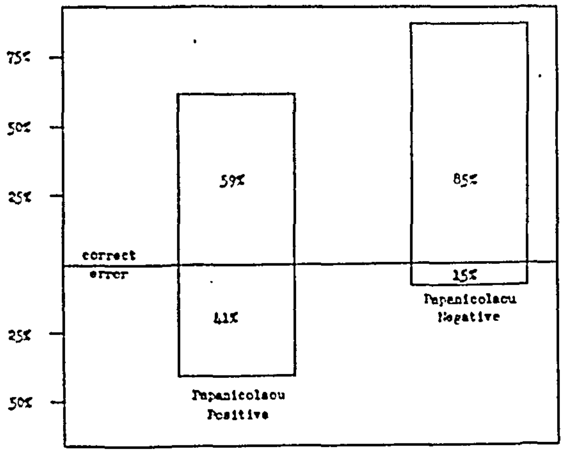

Fig. 5.—Results of gastric cytologic study, on the basis of conclusions drawn.

On some occasions, the cytologic study of the fasting gastric contents has proved itself of value in indicating the need for exhaustive clinical study. For example, the roentgenogram of the stomach of a 62 year old white man (fig. 7), who entered the hospital because of vague upper abdominal discomfort of a nonspecific character, showed some angulation of the lesser curvature, with retention, but the absence of a filling defect precluded the diagnosis of neoplasm. A second roentgenogram failed to clarify the situation. However, microscopic examination of the fasting gastric contents revealed definite malignant cells. The diagnosis of gastric carcinoma was then substantiated gastroscopically and proved at laparotomy.

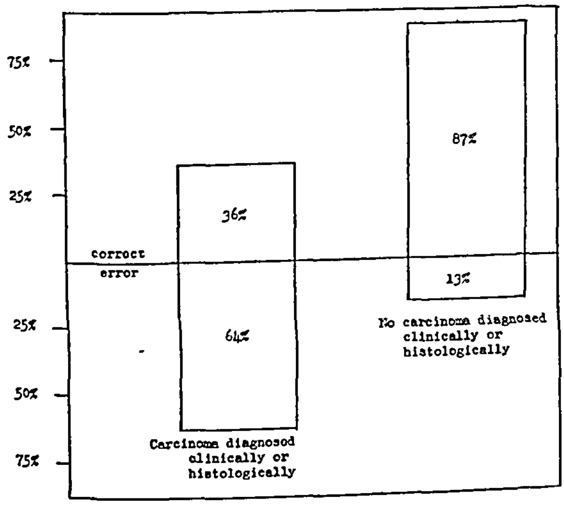

Fig. 6.—Results of clinical studies, on the basis of the conclusions drawn.

COMMENT

The results of the observations to date do not warrant a final conclusion. This series is too small to furnish reliable statistics. The passage of time may well modify the results. Further experience by the pathologist is certain to have some effect. Some of our diagnostic criteria which have been used as a yardstick in judging the technic may prove to have been in error in some cases. This is particularly likely in a large group of cases in which there is no histologic control. A close analysis of our data indicates that actually it reflects only the gross efficacy of the cytologic method for the diagnosis of gastric neoplasm.

There are several factors in addition to those[4b] which were reported that modify the results and cannot be considered actual inherent features of the method itself. First of all, the accuracy with which the pathologist can interpret such smears depends on the extent of his experience. Included in this series are all the early errors that were the result of lack of experience. As more slides were examined the number of errors was gradually diminished. A second factor that must be considered is that in several instances in which clinically there was undoubted gastric neoplasm, it was impossible to obtain good smears because of the retention of food and undigested materials. This was particularly true in those instances in which the neoplasm was so located as to produce obstruction either at the pyloric or at the cardiac end of the stomach. A third point to be mentioned is that in the vast majority of cases only a single aspiration was carried out. This point may not be too significant, in view of the fact that the error both positive and negative was just as great in those instances in which repeated aspirations were done as in the group as a whole when there was only a single aspiration.

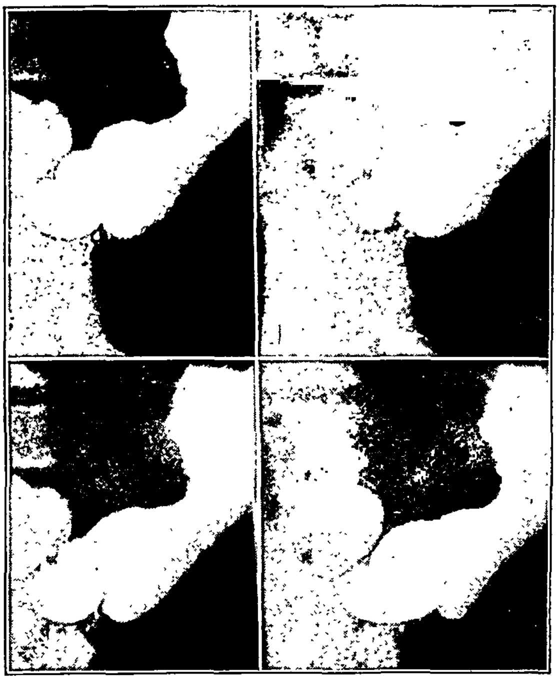

Fig. 7.—Roentgenogram of the stomach of a 62 year old man, showing some angulation of the lesser curvature, with retention; the absence of a filling defect precluded the diagnosis of neoplasm.

This is undoubtedly explained by the fact that aspirations were repeated in the questionable or difficult cases, whereas in the apparently clearcut case a single aspiration was considered adequate.

A final point to be considered is that this series was carried out on a group of patients all of whom had gastrointestinal symptoms. This study was not a survey of asymptomatic persons, and our data should not be interpreted as evaluation of this method in detecting early asymptomatic gastric neoplasms.

In general, however, the procedure has sufficient merit to warrant further trial. False positive reports have been sufficiently numerous to make it inadvisable to plan therapy on the basis of the gastric cytologic study alone. Conversely, a report that malignant cells are present in the fasting gastric contents is an indication that exhaustive studies should be done to rule out the presence of gastric carcinoma. Lastly, the procedure would be valueless and even dangerous except in the hands of a well trained pathologist. Even in such circumstances, difficulties inherent in the procedure will always prevent it from being more than an adjunct to the present accepted methods of examination.

### SUMMARY AND CONCLUSIONS

The cell structure of the gastric juice of 278 patients was examined in three hundred and twenty-six instances for presence of neoplastic cells. Of one hundred and ninety-two aspirations in patients with no clinical evidence of neoplasm the smears were negative in 86 per cent and indefinite or falsely positive in 14 per cent. In forty-three instances in which there was histologic evidence of the absence of gastric neoplasms, the smears were negative in 72 per cent and indefinite or falsely positive in 28 per cent. In 20 cases in which there was clinical evidence of gastric neoplasm, the smears were positive in 40 per cent and negative in 60 per cent. In an additional 41 cases with histologic, as well as clinical, evidence of gastric neoplasm, 35 per cent of the smears were positive and 65 per cent indefinite or negative.

In the present state of development this diagnostic method should not provide the exclusive basis for either the positive diagnosis or the positive exclusion of gastric neoplasm. The method is valueless except in the hands of an experienced and specially trained pathologist.

## ABSTRACT OF DISCUSSION

Dr. Warren C. Hunter, Portland, Ore.: As the diagnosis of gastric carcinoma is fraught with difficulty and uncertainty, every reasonable, safe and prompt diagnostic procedure is worthy of consideration, provided that it is soundly based. Such a procedure is the study of the exfoliating gastric fluid obtained by aspirating the empty stomach. For more than a year, at the University of Oregon Medical School, Dr. Howard L. Richardson and I have been studying such material in a group of unselected patients, most of whom have been furnished us as "unknown." Dr. M. E. Steinberg, of Portland, has carefully studied these cases, but the material came to us as unknown. We are in general agreement with the conclusions of the authors, although, by means of a simple modification which Dr. Block mentioned, the modification of the Papanicolaou smear technic, whereby we embed and section mucus rather than rely on a certainly less reliable smear, our percentage of proved positive results is now about 80. In our experience there is one type of carcinoma that will nearly always be missed by the method, namely, the large obstructive necrotic surface cancers, such as the type Dr. Block mentioned, the exfoliative cells of which are likely to be already in process of breaking down and thus likely to be unrecognizable. I am convinced from experience with a number of such cases that that is the reason why some very obvious carcinomas are missed. The cells are necrotic and cannot be recognized. The microscopic study of gastric mucus is of value as a means of recognizing not only cancer of the stomach but also cancer in the presence of gastritis and gastric ulcer, but, obviously, this is neither the time nor the place to enter into discussion of this phase of the matter. It is my opinion that not until something better than the smear, namely, treating material as tissue, is adopted, will pathologists give any serious consideration to this method for the diagnosis of cancer. They will not because of the fact that Dr. Block mentioned, chiefly the time factor, and what to pathologists is even more unpleasant, and that is the uncertainty of smears because of their varying thickness. Pathologists on the whole will not use smears; therefore, I believe that until we change this method somewhat, even though the principle is good, and until additional personnel is trained, neither this audience nor any other can hope to use such a method generally.

Dr. Maurice Fremont-Smith, Boston: At the Vincent Memorial Hospital in Boston we have been working on the diagnosis of carcinoma of the uterus by vaginal smear for the last five years, and Mrs. Ruth Graham has achieved a great deal of experience in the method and has been able to diagnose carcinoma of the cervix with 90 per cent accuracy. Since we started, about a year and a half ago, to examine gastric secretion, our results have been less satisfactory than Dr. Block's. In a series of about 75 cases, we have achieved only 50 per cent accuracy in a routine series. There is another small series of study cases not yet reported, in which our accuracy has been much more satisfactory than that, but manifestly statistically this method is not yet satisfactory. Our general diagnostic methods for detection of carcinoma of the stomach are puerile. At the Massachusetts General Hospital, in a series of patients operated on ten years ago, only 7 out of every hundred who came to the hospital with gastric carcinoma obtained a five year cure. Something better must be done in early diagnosis of gastric cancer. Continuous exfoliation of cells is taking place in the stomach, both from the normal mucosa and from the majority of malignant lesions, if present. Thus material for a continuous biopsy is present in the gastric secretion. I am not sure that the smear method, as first proposed by Papanicolaou, is the best method. Possibly Dr. Hunter is right in stating that the way to make this diagnosis is not by smear but by the collection of the gastric secretion, precipitating, fixing and sectioning it. The point I want to bring out is that there is material for continuous biopsy obtainable in a large proportion of cases of cancer of the stomach, even in early cases, and it is up to us to find some way of making practical use of this material in the early diagnosis of gastric carcinoma.

Dr. Malcolm Block, Ann Arbor, Mich.: In attempting to evaluate this method, we did fixation along with the smear technic, but after a short period of this, we decided that we should follow Papanicolaou's technic until we could decide whether in our hands the principle could be satisfactory. I briefly went over the fact that we evaluated gastric juice and fixed it in alcohol and followed the usual Papanicolaou procedure. There was a series of experiments in which juice could be obtained by stimulating gastric mucus with alcohol or histamine or by washing out with an irritant or some other material, such as sodium bicarbonate. We carried out a few experiments in the hope of obtaining exfoliative cells in a higher incidence of cases within the usual bounds of technic. We did not obtain exfoliated cells in more instances with whatever technic we used, provided that observations were carried out immediately. Likewise we found that there was no difference in the state of preservation of the cells. This problem is certainly still present, and there are many possibilities for further study of this method.

# ALLERGIC FACTORS IN GOUT

JOSEPH HARKAVY, M.D.
New York

A number of recent papers on gout refer to it as a forgotten disease, implying thereby that it is frequently overlooked. In a series of 100 patients reported by Hench[1] approximately fifteen years had elapsed from the first attack before a correct diagnosis was made. The average age of onset of gout is usually about 40. Although the majority of patients are men, women are not infrequently affected, and the disease has also been described in children.[2] It is generally recognized that the essential features of this condition consist of arthritis with or without podagra, hyperuricemia; deposits of sodium urate crystals in the articular, periarticular and subcutaneous tissues and, in a certain number of cases, of manifestations of cardiovascular or renal involvement. The complete reversibility of the arthritic attacks in the early stages and their irreversibility in the later phases, terminating in crippling chronic gouty arthritis with tophaceous deposits, are features which have been familiar to the physician and the laity for many generations.

Heredity plays an important role in this condition, and one of the most striking phenomena is the transmission in gouty families of hyperuricemia without the disabling symptoms of the disease. Talbott,[3] for example, reported high amounts of uric acid in the blood in 25 per cent of the relatives of gouty persons. Hyperuricemia is likewise frequently observed in a number of clinical conditions in the absence of gout or a family history. Thus patients with glomerulonephritis may have elevated blood uric acid without any gouty arthritis. Persons having leukemia and polycythemia as well as pernicious anemia may also present similar findings.

Nevertheless, the frequency of the association of hyperuricemia with gout serves to differentiate it from other forms of arthritis, although its exact role is not clear. There often is no relationship between the amount of uric acid in the blood and urine and the degree of arthritic involvement. Paroxysms of gout may occur on one occasion with normal and on another with elevated blood uric acid. The latter may be present between attacks when the patient is completely free of symptoms. Acutely affected joints have been found to be apparently free of urates, whereas certain symptomless joints have revealed extensive deposits of urates. Furthermore, there is no constant relationship between the formation or resorption of tophi and acute attacks.

Nor does the increase in bound uric acid reported by Adlersberg, Grishman and Sobotka[4] in 10 cases of gout in conjunction with hyperuricemia help to explain the causation of the gouty paroxysms. This is especially so since they also found abnormal uric acid partitions in about half of their patients with hepatitis, cirrhosis of the liver, prolonged obstructive jaundice and in 1 patient with suppurative cholangitis as well as in a case of leukemia with icterus. While a high titer of bound uric acid was admittedly not a constant finding in the patients with hepatic disease studied and clinical improvement did not necessarily follow a decrease in bound uric acid or vice versa, neither was this the case in all of the gouty patients under investigation. It is generally felt, therefore, that neither hyperuricemia nor abnormalities in the uric acid partition per se can be looked on as the provocative factors in the gouty attacks.

It is therefore necessary to look for some other contributory factors which may be responsible. The sudden explosive nature of the acute gouty seizure, its regression, especially in the early stages, without any residual involvement of the acutely affected joint, and the elicitation of symptoms by certain foods or alcoholic beverages have led certain European students of this problem[5] to suggest that allergy to these substances may play an important role in the pathogenesis of the disease. None of these investigators, however, has reported any cases in which pollen or the synergistic effect of pollen and foods played a role in the initiation of the gouty paroxysms.

The concept that allergy may at times be a factor in the development of gouty attacks carries with it both theoretic and practical significance, particularly when prophylaxis and treatment are considered. It is therefore of great importance to determine whether the various symptoms of gout are due essentially to a disturbance of purine metabolism as such, leading to retention of uric acid in the tissues, or whether the various arthritic, cardiovascular and renal manifestations may be precipitated by allergic reactions in a person handicapped by a hereditary defect in his purine metabolism. The following 3 cases reported in detail may serve to elucidate some of the points in question.

## REPORT OF CASES

CASE 1.—Patient J. S., aged 25, was first admitted to Mount Sinai Hospital in January 1947. As a boy of 12 he suffered with periodic swelling of the knees, ankles, wrists and elbows, designated at the time as growing pains. These recurred three or four times a year and lasted a day or two. In September 1941, at the age of 20, while in the army he experienced an attack of arthritis involving both ankles and knees. This recurred in March 1942 and again in May and December of that year, when both elbows and wrists also became affected. He was discharged from the army in November 1943 with the diagnosis of arthritis. In February 1944 his right knee became swollen and in August of that year migratory joint pains developed which affected both ankles, knees, left foot and left big toe. In October 1945 while riding horseback he experienced sudden severe pain in the chest associated with difficulty in breathing. He was brought to the Northern Duchess County Hospital, New York, where a diagnosis of acute coronary disease was made. The electrocardiogram showed

$T_2$ to be diphasic and $T_3$ inverted. This was interpreted as due to some localized damage in the left ventricle. He was transferred to the Veterans' Hospital in Saratoga, N. Y., from which he was discharged in January 1946 with a rating of 100 per cent disability. Throughout that year he suffered with periodic bouts of arthritis. Just before his admission to Mount Sinai Hospital in January 1947, he experienced pains and swelling of the great toe suggestive of gout. He was confined to bed for twelve days and was discharged improved on February 12, only to be readmitted on Feb. 24, 1947 because acute pains and swelling had developed in the right knee. At this time it was found that he also had involvement of the right great toe and medial aspect of the right ankle. The rest of the physical examination was negative. Laboratory studies showed 13,550 white blood cells, 37 per cent segmented polymorphonuclear cells, 50 per cent lymphocytes, 5 per cent mononuclear cells, 1 per cent basophil cells and 7 per cent eosinophils. The blood uric acid on Feb. 25, 1947 was 10.0 mg. per hundred cubic centimeters, on February 27, 7.2 mg., and on February 28, 6.8 mg. per hundred cubic centimeters. The blood cholesterol was 239 mg. per hundred cubic centimeters. Blood urea nitrogen was 8 mg. and creatinin was 1.3 mg. per hundred cubic centimeters. The electrocardiogram was normal.

The patient was given $\frac{1}{50}$ grain (1.2 mg.) of colchicine every two hours for three doses, and on the following morning the joint pains subsided to a considerable extent. After a few days of hospitalization there was gradual improvement, and he was discharged with the diagnosis of gout.

In view of the fact that the most severe attacks occurred characteristically during the spring and fall, it was thought that perhaps the pollen prevalent during that period might be responsible for his symptoms rather than excess of food and drink traditionally considered as responsible factors. Despite a negative personal and family history for allergic diseases the patient was studied for the presence of hypersensitiveness. Tests disclosed positive reactions to a number of foods and inhalants, among which were wheat, timothy and ragweed pollen. It was felt that if sensitivity to pollen or wheat played a role in the arthritic attacks, then direct exposure to these substances should evoke an attack of arthritis in a patient whose shock organ was confined to the joints, just as similar contact would elicit hay fever or asthma in a person whose shock tissue was the respiratory tract. With the consent of the patient, it was decided to give him injections of the pollens in question before putting him on any diet excluding the reacting foods.

On March 21, 1947, while he was free of symptoms, his blood was examined for uric acid and found to contain 4.2 mg. per hundred cubic centimeters. On March 24, 1,000 units (protein nitrogen units, i. e., 1 unit is 0.01 mg. of phosphotungstic acid precipitable nitrogen) of timothy were introduced parenterally. At about 2 a. m. in the morning of March 25 he was aroused with severe pain in the left ankle which increased progressively in severity, followed by considerable swelling, tenderness and heat. There were also swelling and itching in the arm at the site of the injection of the pollen. The blood uric acid rose to 9.9 mg. per hundred cubic centimeters. He took four $\frac{1}{50}$ grain tablets of colchicine, and the swelling subsided within twenty-four hours, only to flare up again on March 28. He repeated the colchicine, and again the swelling receded. He became completely well on March 30, 1947.

The effect of the injected timothy raised the question whether the ingestion of wheat, which is botanically related to timothy and to which he showed a positive skin reaction, had anything to do with the elicitation of the joint symptoms. He was therefore advised to eliminate wheat products. This he did, and he felt perfectly well until April 9, when he ate some bread and cake. A swelling of the right knee developed. The attack, however, was relatively mild and disappeared in twenty-four hours. At this time the blood uric acid was 9.2 mg. per hundred cubic centimeters.

On April 12 he was given an injection of 0.2 cc. of buffered sodium chloride solution used in extracting the pollen as a control, with no ill effects. This procedure was repeated April 14 with equally negative results.

On April 16 while on a wheatless diet he was given 1,750 units of timothy pollen, subcutaneously. This was followed twenty-four hours later with swelling and itching of the arm at the site of injection but without any arthritic manifestation. The uric acid was 7.7 mg. per hundred cubic centimeters. On April 21 he received 1,500 units of ragweed pollen. The arm at the site of injection became swollen, but again no gouty attack followed.

On April 23 he felt well and was told to resume eating wheat. Twenty-four hours later pains developed in the instep of the left foot. The dorsum was swollen and hot and veins distended. The blood uric acid was 7.8 mg. per hundred cubic centimeters. Application of heat and elevation of the foot relieved him. He took colchicine, and the pain and swelling subsided completely on April 26, 1947. When seen on April 28 he was free of symptoms, although he continued to eat wheat. This could be explained on the basis of temporary desensitization as a result of the recent joint attack. While in this asymptomatic state he received 3,000 units of timothy pollen subcutaneously. Eight hours later, at 2 a. m. on April 29, he was aroused with a severe attack of pain involving the upper and outer area of the right foot. The pain was so excruciating that he was unable to move. He also experienced nausea and diarrhea and could not eat. The inoculated site on the arm was markedly swollen and hot. Because of the diarrhea he was afraid to take colchicine and instead was given camphorated opium tincture with relief. On April 30 the pain and swelling gradually shifted to the right ankle and on May 1 it involved the right great toe, preventing him from walking. The skin over the great toe presented a bluish discoloration. The blood uric acid was 6.4 mg. per hundred cubic centimeters. These symptoms persisted with varying intensity until May 7, when he began to feel better; on May 9 he felt perfectly well again. He automatically had stopped eating wheat at the inception of this attack.

On May 12, after a period of three days of well-being, while still on a wheatless diet he was again given an injection of 2,000 units of ragweed. The following day there was a definite local swelling in the arm but no sign of arthritis. On May 16 he was told to eat wheat again. This time six days elapsed before a moderate swelling of the right knee developed. Such a sequence of events is frequently seen in allergic patients who, after abstaining from an offending food for a period of time, require more prolonged contact with the incriminating allergen before having symptoms again. On May 23, while still eating wheat, he was given 2,000 units of ragweed pollen. Within eight hours the pain and swelling in the right knee markedly increased. He was unable to move it more than 1 inch. After he had taken four doses of colchicine the swelling of the knee subsided, but on May 25 it shifted to the right foot and right elbow. His temperature rose to 102 F. and remained at that level until the next day, when it dropped to 100 F.

The blood sedimentation rate was 42 mm. in one hour (Westergren method). The blood examination showed 11,850 white blood cells, the differential count of which was as follows:

| | Percentage |
|---|---|
| Nonsegmented polymorphonuclear cells | 5 |
| Segmented polymorphonuclear cells | 50 |
| Eosinophilic polymorphonuclear cells | 4 |
| Lymphocytes | 37 |
| Monocytes | 4 |

The temperature fell gradually, and on May 28 the inflammatory signs in the ankle and the knee disappeared, but the right elbow remained swollen, and involvement of the left knee followed. Although colchicine was administered again it was ineffective. He was therefore given a subcutaneous injection of 0.5 cc. of epinephrine in the region of the swollen knee. This immediately relieved the throbbing pain and helped to reduce the swelling. Injections of epinephrine were thereafter repeated until all symptoms finally subsided, on June 6, 1947.

Since he had stopped eating wheat after the onset of this severe arthritic attack and at this point had been on a wheat-free diet for three weeks it was decided, despite the presence of timothy pollen in the air, to attempt to desensitize him to the latter as well as to ragweed pollen, and at the same time to study the effect of the simultaneous injections of these two pollen extracts. On June 13, two days after he had received 100 units of timothy and 100 units of ragweed pollens, severe swelling of the left ankle developed, followed on June 14 by that of the left great toe. The blood uric acid at that time was 5.7 mg. per hundred cubic centimeters. Epinephrine was again used effectively with relief from pain. The involvement in the toe continued for the next two weeks, and on June 27 the right elbow became slightly tender and swollen. Complete remission of this attack took place on June 30.

After a symptomless interval of about a week he was again given 100 units of timothy and 100 units of ragweed (July 7). This was followed the next day by injection of 200 units of ragweed. Two days later severe swelling of the right knee developed, followed by marked suppression of urine. A specimen of the latter showed albumin (3 plus). The oliguria continued for three days and gradually cleared, whereas the involvement of the knee persisted till July 25. Throughout this period the joint pains were controlled with epinephrine in oil. Examination of the blood uric acid on August 11, when he was perfectly well, showed 8.1 mg. per hundred cubic centimeters. The urine was normal.

He felt well till September 2, when he experienced slight pain in the right ankle, which disappeared spontaneously after several days, although he had stopped eating wheat. This attack was regarded as due to heavy ragweed pollination. The examination for uric acid on September 3 showed 13 mg. per hundred cubic centimeters. Since this episode he has been perfectly well on a wheatless diet to the present writing (January 1948). Examination of his blood on December 5, 1947 showed 5.9 mg. of uric acid per hundred cubic centimeters.

*Summary.*—A man aged 25 was admitted to the hospital because of an attack of arthritis involving the great toe. He gave a history of periodic bouts of similar joint involvement in the past and an attack of angina pectoris in October 1945. Examination suggested the diagnosis of gout. This was supported by the presence of hyperuricemia. The blood count revealed eosinophilia (7 per cent). Because of the latter and the fact that the most severe attacks occurred during the early summer and fall the possibility of hypersensitiveness to the prevailing pollens was suspected, despite absence of a personal and family history of allergy. Investigation disclosed positive reactions to foods and inhalants, of which wheat, coffee, timothy and ragweed pollen were found to be most significant. Ingestion of wheat induced a moderate attack of monoarticular gout with rise in uric acid. Ingestion of wheat plus the subcutaneous injection of timothy or ragweed pollen extract up to 2,000 or more units resulted in severe polyarticular gout involving the great toe and accompanied by elevation of uric acid. Combined injection of 100 units of ragweed and 100 units of timothy pollen during the grass pollinating season induced similar arthritis seizures and on one occasion was followed by marked suppression of renal function and albuminuria lasting three days. Separate inoculation of either ragweed pollen or timothy pollen, when the patient was on a wheat-free diet, resulted merely in swelling at the site of injection and no other manifestations. With the termination of the pollen season and avoidance of wheat the patient became free of symptoms.

CASE 2.—J. R., aged 45, was first seen in May 1944. He had influenza in 1918 which was followed by otitis media and impairment of hearing. The latter became worse in 1928 as a result of an infection of the upper respiratory tract which also left him with an involvement of the left antrum. As a sequence to the antral infection pain developed in the great toe which was diagnosed as gout. This attack was succeeded by others which were so severe as to disable him for as long as ten days at a time. The arthritic manifestations were preceded by stuffiness of the nose and a postnasal discharge. In November 1940 he suffered with polyarticular gout involving the big toes of both feet, the wrists and the knees which confined him to bed till February 1941. He was treated with colchicine and neocinchophen with good results. After his acute attacks subsided he went to the New York Hospital for observation. Here it was discovered that he had chronic hypertrophic rhinitis, chronic nasopharyngitis, pansinusitis and pronounced mixed deafness. The heart, lungs and abdomen were normal, and roentgen visualization of the gallbladder proved negative. The antrums were washed and the left one was found to contain purulent secretion. Inasmuch as the involvement of this maxillary sinus was found to be associated with a diseased left upper molar, the latter was extracted. An antrotomy was also performed (June 2, 1941) and several large polyps were removed from the interior of the antrum.

Roentgen examination of the left foot at this time disclosed several small areas of decreased density at the proximal end of the first phalanx along the mesial border of the left foot. This was diagnosed as gout. Laboratory studies showed blood uric acid levels of 6.8 mg. and 5.4 mg. per hundred cubic centimeters respectively. The sedimentation rate was 61 mm. On discharge from the New York Hospital he was advised to have the sinuses treated and to stay on a low fat and low purine diet.

From 1942 to 1944 the infected antrum was washed from time to time by his rhinologist, who found that any exacerbation of the chronic sinusitis was followed by a severe attack of gout.

About the beginning of May 1944, after one of his acute sinus attacks, the patient experienced severe pain in the right wrist. In view of the fact that in that season of the year relatively little infection was present the question arose whether exacerbation of the sinus disease, which was responsible for similar previous gouty attack, was due to endogenous or some exogenous factors such as pollen sensitization. Investigation for the presence of hypersensitiveness was therefore undertaken despite a negative personal and family history of allergy.

Skin tests revealed that the patient reacted to various inhalants such as tree pollens, timothy and ragweed, as well as foods. These findings suggested that the sinusitis as well as the sneezing and wheezing together with the "sour stomach" which frequently preceded and aggravated the arthritis attacks during the summer months might be explained on a basis of sensitization to the substances causing positive reactions.

On June 10, 1944 he was placed on a diet which excluded the suspected allergenic foods and immunization was instituted against ragweed pollen. He was also given injections of a vaccine of Staphylococcus aureus organisms cultured from his sinuses.

He felt perfectly comfortable until September 28, when mild asthmatic seizures developed, which disappeared on Nov. 11, 1944. Thereafter he was well until Jan. 8, 1945, when after an infection of the upper respiratory tract he had a moderate attack of arthritis involving the right knee, which cleared up on Jan. 12, 1945.

Immunization against timothy and plantain was begun in February 1945. This was continued uneventfully until March 12, when after an injection of 1,200 units of timothy pollen, he experienced cough and shortness of breath together with pain in the right knee, which improved after two days. The injections of timothy pollen were therefore resumed at a lower level of dosage, and on March 29 immunization against tree pollens was started at the same time. After receiving 200 units of tree pollen extract on April 23, 1945 the patient experienced pain in the right foot, which became so severe and persistent that it was decided to discontinue the injections of tree pollen extract. This was followed by notable improvement, and he remained well till May 7, 1945, when, after an inoculation of

16,000 units of timothy extract, acute bursitis of the right elbow suddenly developed, which lasted for one week. This was interpreted as a local specific reaction to an overdose of timothy pollen. Injections of the latter were therefore discontinued. On June 11 desensitization against ragweed pollen was begun. He was asymptomatic until Aug. 23, 1945, when despite the fact that he had received 4,000 units of ragweed pollen he began to sneeze and experienced stuffiness of the nose, cough and pain in the right great toe. This continued until September 4, when both the nasal and the toe symptoms disappeared.

On October 18 he went to the country for a week end and went off his diet, after which there developed an attack of arthritis affecting the right wrist, lasting for three days. He remained well until Dec. 1, 1945 when after the ingestion of oysters he experienced severe pain in the right foot which confined him to bed for two days. On December 23 he contracted a sore throat. Six days later he experienced swelling of the right hand, affecting the fourth metacarpal joint. This slowly improved.

In view of the fact that during the spring of 1945 injections with combined tree and timothy pollen had to be discontinued because of the appearance of joint symptoms, immunization against tree pollens was begun early in November 1945 and continued through February 1946. On February 12 after a dose of 1,500 units of mixed tree pollens, a moderate attack of asthma developed. This amount was reduced and subsequently increased without any mishap until March 7, when he received 2,500 units of mixed tree pollen extract, consisting of ash, birch, poplar and oak tree pollens together with 100 units of timothy. This was again followed by severe involvement of the right knee. Timothy pollen inoculations were therefore immediately stopped. On March 25 when he reached the dose of 3,000 units of mixed trees the involvement of the right knee, which had been subsiding, flared up again; it persisted till April 30, when it was followed by involvement of the left ankle, which lasted till June 5, 1946.

Because of the experience with the timothy and tree pollen inoculations he decided against further treatment with ragweed extract. As a result symptoms of hay fever developed about Oct. 2, 1946, followed by an attack of podagra affecting the right great toe.

He was not seen again until September 1947 when he gave the following history of the interval. In March 16, 1947 pain in the right elbow associated with bursitis developed. This was followed by swelling of the right hand, which disappeared on April 4. The bursitis persisted until June 4, 1947, when it cleared up completely. During May and June he was unable to walk because of pain in both feet. About July 1, swelling of the left index finger developed and one week later bursitis involving the left elbow. The pain in the left finger subsided on July 8, only to be succeeded by migrating pains affecting the right elbow and both knees; this disappeared about July 25. Throughout this entire period he suffered with asthma, which was relieved by the use of a proprietary preparation containing ephedrine, phenobarbital and aminophylline. He was relatively well till the middle of August, when he experienced symptoms of hay fever, difficulty in breathing, sour stomach and an exacerbation of the bursitis of the left elbow as well as pain in the right great toe. He attributed the sour stomach to coffee and beef, to which he showed positive skin reactions.

*Summary.*—A man aged 45 presented himself because of recurrent attacks of gouty arthritis including podagra following exacerbations of chronic sinus disease which had resulted from previous infections of the respiratory tract. A left-sided antrotomy with improved drainage helped to diminish the frequency of the gouty episodes. Nevertheless he still suffered severely during the spring and fall, when the attacks were preceded by stuffiness of the nose and wheezing respiration. Investigation disclosed sensitivity to tree, timothy and ragweed pollen as well as various foods. Injection of an overdose of tree pollen extract in the process of immunization was followed by acute gouty attacks involving the knee, the ankle or the elbow as well as the great toe. Similar arthritic reactions accompanied by sneezing and/or asthmatic episodes followed the administration of an overdose of timothy extract or combined injections of tree and timothy pollen extracts.

Case 3.—E. W., aged 41, a trained nurse, was admitted to the allergy clinic because of recurrent sneezing which was especially pronounced during July, August and September. The family history revealed that her maternal grandmother had asthma and her paternal grandmother, uncles and father had had arthritis.

As a child she suffered with so-called rheumatic joints and recurrent colds accompanied by sinusitis. When she entered training in 1929 her sinuses were examined and both antrums were found infected. Washings yielded mucopurulent material which on culture showed Staph. aureus, diphtheroids and Staphylococcus albus. In view of the fact that the tonsils were regarded as a source of infection, tonsillectomy was performed in October 1929. On one occasion after receiving a prophylactic injection of typhoid vaccine she experienced stiffness in all her joints. This receded with the exception of the pain in the right wrist, which bothered her throughout her training.

An attack of grip in 1934 was followed by severe coughing spells. Roentgen examination of the lungs disclosed an infiltration in both apices which was diagnosed as tuberculosis. The sputum, however, was never positive for tubercle bacilli. She left training and went to a sanatorium in Saranac, N. Y., where she remained for two years, returning in 1936. Early in 1941 she had a cholecystectomy for lithiasis followed by a pulmonary embolism and pleural effusion. After a stormy convalescence she improved except for the persistence of her sinusitis and pains in the right hand and knee. Because of seasonal recurrences of the sinusitis she suspected that it might be due to allergy and submitted herself for study. On investigation she was found to be sensitive to dust, trees, timothy and ragweed pollen as well as to foods, the most important of which proved to be milk and coffee.

In July 1941 she experienced pain in the great toe of the right foot. This recurred during the hot and humid days of July and August. Inasmuch as the symptoms were suggestive of gout her blood was investigated for hyperuricemia. The specimen examined July 8, 1941 showed a blood uric acid level of 5.8 mg. per hundred cubic centimeters. After another attack of polyarthritis during the ragweed season which implicated right wrist, knee and right great toe, the blood uric acid was 7.2 mg. per hundred cubic centimeters (Aug. 13, 1944).

Immunization was undertaken against dust, timothy and ragweed pollen. She was also given an injection of an autogenous vaccine made from the organisms recovered from the sinus washings. While under treatment she manifested extreme sensitiveness to dust and ragweed pollen. On several occasions, severe constitutional reactions developed after injections of 0.1 cc. of 1:1,000 solution of dust extract. The ragweed pollen extract could not be increased beyond 20 units. Despite the small immunizing pollen doses she became relatively free of the nasal symptoms as well as the joint pains. On April 17, 1947 she was revaccinated with smallpox vaccine. This was followed by an attack of muscle and joint pains, which greatly debilitated her. To regain her vigor she decided to take a glass of milk every afternoon, although she knew that she was sensitive to it and had refrained from drinking it for fifteen years. After partaking of one glass of milk every afternoon for four days she experienced severe pains in the right wrist and right knee as well as in all her neck muscles, which confined her to bed for a week. After recovery she decided to discontinue all immunization to pollen and dust because she was never certain when she would get a constitutional reaction. She has, however, continued to exclude the allergenic foods and has been free of arthritic attacks.

*Summary.*—A nurse, aged 41, with a family history of arthritis and asthma, presented symptoms of hay fever, vasomotor rhinitis and chronic sinusitis associated with bouts of gouty arthritis with hyperuricemia. These appeared (1) during the timothy and ragweed season, (2) after smallpox vaccination and (3) after drinking milk. Improvement followed the elimination of foods to which she was sensitive and immunization to specific pollens and dust.

### COMMENT

In the foregoing cases it was possible to precipitate acute attacks of gouty arthritis and hyperuricemia by specific allergenic excitation. Ingestion of various amounts of purine-and-fat-containing foods proved to be harmless as long as the sensitizing substances were avoided. This suggested that the persons under investigation were allergic and that their shock tissues were located in the articular structures. Evidence to this effect was obtained in the personal and family history of allergy in cases 2 and 3. In case 1, despite the absence of such a history the possibility that allergy might be a factor was considered because the most severe attacks occurred during the spring and late summer coincidental with the pollen season, and on one occasion were accompanied by eosinophilia. Support for this hypothesis was found not only in the demonstration of positive skin reactions to pollens and foods, such as wheat, but also in the precipitation of acute gouty paroxysms by specific contact with these exciting agents. Thus within twenty-four to thirty-six hours after eating wheat this patient invariably experienced a mild monoarticular involvement. In such circumstances it was always possible to induce severe polyarticular gout, including podagra and hyperuricemia, by the injection of either timothy or ragweed pollen solutions in two or three thousand unit doses, whereas when he was on a wheatless diet injections of timothy or ragweed pollen extract were without any effect. However, the combined administration of ragweed and timothy pollen extracts, in doses as little as 100 units each, during the timothy pollen season resulted in polyarticular manifestations of gout on one occasion, and on another besides the arthritis a suppression of urine and albuminuria which lasted three days. The latter may have been due to some vascular reaction in the kidneys in response to pollen sensitization analogous to the periarticular edema and venous dilatation in the acutely gouty joint. It is possible also that the anginal seizure which this patient experienced in October 1945 associated with inversion of $T_2$ and $T_3$ in the electrocardiogram likewise represented a vascular response to some allergenic stimulation. In other words, it is not improbable that in these patients the articular, renal and cardiac manifestations, just as the gouty arthritis, could be looked on as the effects of vascular reactions in different shock tissues induced by sensitization by a variety of exciting agents. It follows, therefore, that no involvement of these extra-articular tissues need be expected unless they happen to be shock organs.

That the gouty attacks may be induced not only by pollen and foods but also by bacterial sensitization is illustrated in cases 2 and 3 of this series. In both of these patients arthritic manifestations followed exacerbations of chronic sinusitis as a sequence to either acute infection of the respiratory tract or tree and grass pollen sensitization during the spring and summer. In case 2 the gouty attacks were frequently preceded by nasal stuffiness or wheezing respiration. Injections of an overdose of tree or grass pollen extracts evoked joint symptoms as well as sneezing and asthmatic breathing. The precipitation of reactions in the respiratory tract concurrently with those in the joints by the same allergenic excitants is strongly suggestive that the responses in these various shock organs were influenced by a similar mechanism. The lack of any evidence of respiratory allergy in case 1 may simply be due to the fact that this patient's respiratory tract was not a shock tissue. Nevertheless, in this as in the other cases, the arthritis seemed to be due to sensitization to pollens and foods and was controlled by local subcutaneous injection of epinephrine,almost as well as with colchicine.

One of the most significant facts made apparent by this study is the severity of reactions and number of shock organs which participated after the simultaneous exposure to several allergens. This synergism was illustrated in case 1, when both polyarthritis and renal symptoms accompanied by hyperuricemia developed, after injection of combined timothy and ragweed pollen, and cases 2 and 3 when nasal and respiratory symptoms such as wheezing appeared together with joint symptoms after the ingestion of specific foods or injections of tree and timothy pollen. This is comparable to the synergistic effects noted as a result of multiple sensitization in uncomplicated allergic states such as asthma or vasomotor rhinitis. Other similarities between the latter and gout are to be found (1) in the presence of uric acid retention in certain asthmatic persons as reported by K. Hajos and Kurti, Kleyn and Storm van Leeuwen, which, however, needs further verification and elucidation; (2) in the influence which nonspecific endogenous as well as exogenous exciting factors such as psychic stress, surgical operations and temperature changes may play in precipitating these different clinical syndromes. Any one of these nonspecific excitants may either accentuate the asthmatic or gouty attacks originally induced by allergy to certain food or inhalants or condition the respective shock tissues to subsequent specific sensitization.

If it may be assumed that the fundamental reaction in the joints of the patients under investigation was due to hypersensitiveness, it may be inferred that any subsequent deposition of urates in the affected articular and other structures such as the kidney would be probably secondary. This concept finds support in the observations of Weil[6] and his collaborators, who observed fibrinoid degeneration of the collagen, surrounded by fibroblasts, histiocytes, plasma cells and granulocytes in the histologic sections of a gouty joint, regarded by them as due to allergy. The classical picture of chronic tophaceous gout in patients like those described can therefore be looked on as the result of irreversible inflammatory changes in the joints, originally of allergic origin, which favor the precipitation and deposition of urates. This sequence of events may be compared to bronchial asthma, in which recurrent attacks may lead to irreversible changes characterized by pulmonary fibrosis and emphysema.

Uric acid itself is considered by some investigators of this disease as a dead product in the attack. Others, such as Chini, look on uric acid as an activating agent concerned with fixing of the allergens in certain pre-

---

disposed areas because of its capacity to produce increased tissue permeability. According to this investigator uric acid and the allergic factors compliment each other and must be considered equally responsible in the gouty attacks. Such an interpretation, however, seems to be contradicted by the fact that despite the presence of a high level of uric acid in the blood, the gouty person, on the one hand, may be free of any symptoms, and, on the other, may have attacks when on a so-called normal or low purine diet with normal blood uric acid. This would suggest, in the absence of any evidence that uric acid has any allergenic properties, that the role of uric acid is passive rather than active. Emphasis should therefore be directed to the specific and nonspecific excitants of either exogenous or endogenous origin, which may play the active role in the development of the gouty symptoms.

Inasmuch as a disturbed purine metabolism, whether on a constitutional or other as yet unexplained basis, usually accompanies this disease, the gouty person of the type referred to may be regarded as a potentially allergic person whose joints constitute the major shock tissue with a coincidental uric acid diathesis. The crippling arthritis of the tophaceous stage in such a patient may represent the sequela of undetected repeated allergenic insults. The ensuing local complications may in turn be attributed to the mechanical and otherwise irritating effects of the uratic deposits.

## SUMMARY

It is generally recognized that attacks of gout in predisposed persons may be precipitated by a large number of factors. These may be foods, certain alcoholic beverages, excessive ingestion of fats, surgical operations, drugs such as mersalyl, ergotamine tartrate given for migraine, insulin, liver injections, blood transfusions, disturbance in the electrolyte and water balance, trauma and exposure to dampness and cold. The mode of action of each of these exciting agents varies and is not always clear. It is therefore desirable whenever possible to determine the underlying mechanism involved.

In a study of 3 patients, 2 men and 1 woman, it was possible to demonstrate that allergy to specific foods and pollens as well as to infection played a conspicuous role in the development of the gouty manifestations associated with hyperuricemia. Acute attacks of gout could be induced by the deliberate subcutaneous injection of several pollen extracts at the same time or by the synergistic action of allergenic foods and pollens. In addition to the joint symptoms reactions in the kidneys characterized by temporary urinary suppression with albuminuria were observed in 1 patient as a consequence of pollen inoculation. In another instance the administration of an overdose of pollen was followed by simultaneous response in the nasal and pulmonary as well as in the articular structures. This suggested that the swelling of the gouty arthritis in these patients and the renal and respiratory manifestations were the result of vascular tissue reactions mediated by a similar allergic mechanism. The role of uric acid in the gouty attacks is discussed. The symptomatic treatment consisted of administration of colchicine and local injection of epinephrine. The causal therapy included the elimination of offending foods and pollen immunization.

# TOXIC REACTIONS DURING STREPTOMYCIN-SULFADIAZINE THERAPY OF BRUCELLOSIS

NORMAN B. McCULLOUGH, M.D.
and
C. WESLEY EISELE, M.D.
Chicago

The toxic effect of streptomycin on the eighth cranial nerve has been well known since early in its clinical use. Published opinions indicate that the toxicity of streptomycin to the central nervous system is confined almost entirely to this nerve, predominately to its vestibular branch.[1] Nevertheless, a few isolated instances of other neurologic involvement have been reported. Hunnicutt and co-workers[2] have published a fatal case of toxic encephalopathy apparently caused by streptomycin. Postmortem examination revealed focal areas of rarefaction and necrosis throughout the brain. Finland and co-workers[3] reported a patient in whom severe vertigo, syncope and right-sided clonic convulsive seizures occurred on two occasions during the intravenous injection of streptomycin. In patients with meningitis receiving streptomycin intrathecally, neurologic disorders arising during the course of treatment ordinarily are attributed to the disease, but in some instances it is not unreasonable to suspect that the symptoms may be a toxic manifestation of the drug. For example, in the report by Weinstein and Perrin[4] of 3 cases of meningitis due to *Pseudomonas pyocyanea* treated with streptomycin and sulfadiazine, circumstances in their second case warrant a strong suspicion that the neurologic complications were due to the drug rather than to the disease. In a relapse of the meningitis occurring thirty-two days after initial treatment, streptomycin and sulfadiazine were again administered.

> Twenty-three days after resumption of intrathecal treatment, a series of generalized convulsions, lasting about an hour occurred, and was followed by stupor. A lumbar puncture revealed 550 red cells and 550 white blood cells per cu. mm. (91 per cent lymphocytes). There were no localizing neurological signs or paralysis. Within 24 hours consciousness returned but the patient was euphoric and had some difficulty in recognizing people. Intrathecal streptomycin was discontinued immediately after the convulsive episode.[4]

The relatively low spinal fluid leukocyte count is in contrast to counts of 6,000 to 14,000 during the early days of the relapse. This, together with the absence of a rise in fever, further leads one to suspect that this complication may have been due to the streptomycin. It may be significant that this patient was receiving sulfadiazine simultaneously.

Paresthesias of the face, particularly of the circumoral region, the tongue and even of the extremities are not infrequent.[5] Although this is well known, its possible significance as evidence of widespread

toxicity to the central nervous system has been largely ignored.

During the course of treatment of brucellosis with the combined use of streptomycin and sulfadiazine, we have encountered toxic reactions of the nervous system which seemed to be out of proportion to the small doses of streptomycin and to involve more widespread areas of the brain than has generally been recognized. In 2 cases severe encephalopathies were encountered within a few hours after the initial dose of streptomycin.

### REPORT OF CASES

Case 1.—Miss I. K., a 24 year old woman, has been observed at the University of Chicago Clinics since Sept. 1, 1947. (This patient was reported by Howe and his co-workers,[6] case 3, and also by Apter, Halstead, Eisele and McCullough.[7]) She acquired brucellosis (Brucella suis septicemia) in March 1945 while in the Navy working in a brucella research laboratory. The initial illness was severe and prolonged and included episodes of intense headache and stupor, suggestive in retrospect of an encephalopathic process. In the succeeding two years there were at least ten febrile recurrences. She has continued to be totally disabled and to complain of persistent fatigue, recurrent headaches, multiple joint pains, insomnia, mental sluggishness and remarkably poor memory. Laboratory and clinical evidence of organic brain damage in this patient has been presented elsewhere.[7]

In November 1947 a course of simultaneously administered streptomycin and sulfadiazine was instituted. Twenty-four hours after sulfadiazine therapy (6 Gm. per day) was begun, streptomycin therapy was started. On the first day, 3 Gm. of streptomycin were given in divided doses, on the second day 4 Gm. and then, because of toxic signs, the dose was reduced, and for the next eight days 2 Gm. were given daily. The sulfadiazine therapy was continued for an additional eleven days, with blood levels approximating 10 mg. per hundred cubic centimeters. One week after streptomycin therapy was stopped, additional 4 Gm. were given during a twenty-four hour period for the purpose of verifying and further evaluating the toxic reaction.

During the second day of streptomycin therapy, the patient presented alarming symptoms of central nervous system disturbance, consisting of severe headache, semistupor, mild disorientation, bilateral ptosis of the eyelids, eye muscle weakness with difficulty in convergence and diplopia on lateral gaze, blurring of vision, paresthesias and pronounced hypalgesia to pinprick on the entire face and forehead, most pronounced in the perioral region, tremulousness of the lips bordering on fibrillatory movements, tinnitus and paresthesias in the extremities. A lumbar puncture was done; the dynamics were normal, the cell count was 4 lymphocytes per cubic millimeter, and the results of chemical, colloidal gold and Kahn tests were normal. We questioned seriously whether this treatment should be abandoned, but in view of the patient's long incapacitating illness and a reasonable doubt that this reaction could be due to the treatment, the dose of streptomycin was reduced to 2 Gm. per day and continued for eight more days. On this reduced dose the symptoms and signs diminished but did not disappear.

One week after streptomycin therapy was stopped, but while sulfadiazine was still being administered, streptomycin was again given for a twenty-four hour period (0.5 Gm. every three hours, total dose 4 Gm.). After the second dose, the former symptoms and signs reappeared, and by the end of the twenty-four hour period the previously described clinical picture was again reproduced in all essential details. The diplopia and the perioral hypalgesia to deep pinprick persisted for two weeks, eventually disappearing.

Case 2.—Mrs. C. B., a 50 year old farmer's wife, has been examined at frequent intervals at the University of Chicago Clinics since November 1944. (This patient was also reported by Apter, Halstead, Eisele, and McCullough.[7]) The present illness began in 1938 and was characterized by an acute onset with temperature ranging as high as 104 F., severe headache, muscular pains and loss of weight. Although bacteriologic proof has not been obtained in this patient since she was first seen by us seven years after the onset, the diagnosis of chronic brucellosis rests soundly on the following data: an adequate exposure history consisting of ingestion of raw milk from a herd subsequently shown to be heavily infected with Bang's disease, a rising agglutinin titer from completely negative at the onset of the illness to a titer of 1:320 several months later (both tests were performed in the Illinois State Laboratory of Public Health) and a chronic febrile incapacitating illness in a previously well patient. Following her acute illness, her complaints have been many, persistent and disabling and included headache, weakness, exhaustion, insomnia and radicular pains. Recurrent episodes of low grade fever occurred. For the past seven years she has recognized increasing difficulties in reading, writing, calculating and remembering. Sample tests for immediate recall, memory and calculation yielded retarded and impaired responses. The significant neurologic observations consisted of decided concentric constriction of the visual fields; unequal pupils; minimal and sluggish reaction of the right pupil to light; tremulousness of the lips during mimetic expressions; bone conduction greater than air conduction on the left; generalized muscular weakness and hypotonia; bilateral symmetric atrophy of distal portions of all extremities most pronounced in the intrinsic musculature of the hands and feet; hyperactive knee jerks; the right ankle jerk absent and the left barely elicited; absence of vibratory sensation over terminal phalanges, ulnas, radiuses, tibias and fibulas; impairment of position sense in all extremities; pain, thermal and light touch sensations diminished on the face, thorax and abdomen and greatly impaired distal to the elbows and knees; awkwardness in the performance of coordinative functions, and hesitant and mildly ataxic gait. Spinal fluid studies on four occasions revealed no biologic alterations. Electroencephalographic tracings taken a year apart were consistent with a diagnosis of generalized encephalopathy. The Halstead Impairment Index[8] of biologic intelligence was 0.8.

In February 1948 she was given the combined streptomycin and sulfadiazine treatment. Sulfadiazine was started with a daily dose of 6 Gm. The next day, streptomycin therapy was started with a dosage of 2 Gm. per day and continued for fourteen days (total dose, 28 Gm.). Sulfadiazine therapy was continued for an additional four weeks, and blood levels were maintained at approximately 10 mg. per hundred cubic centimeters.

On the second day of streptomycin treatment, the patient experienced a severe generalized headache, dizziness, blurring of vision, diplopia on lateral gaze, ptosis of the eyelids and complete inability to roll the eyes upward. She complained of stiffness and soreness of the neck, and a moderate degree of nuchal rigidity was present. A sharp but brief rise in temperature occurred during an otherwise afebrile period. These signs and symptoms appeared after 2 Gm. of streptomycin were administered and became maximal after 4 Gm. They persisted but did not progress during the remainder of the course of streptomycin and thereafter gradually disappeared. Spinal fluid examination on the second day showed normal dynamics, an absence of cells and normal serologic and chemical reactions.

Toward the end of the course of streptomycin tinnitus and vertigo developed. Repeated tests of labyrinthine function showed no abnormalities until the course was completed. Symptoms then became so severe that she was unable to walk without aid, and tests showed nonresponding labyrinths. This disability has persisted to the present time, five months later.

In addition to the foregoing 2 cases, an odd neurologic complication has been observed in another patient.

Case 3.—Mrs. C. M., a 49 year old farmer's wife, has been followed intermittently at the University of Chicago Clinics since August 1946. Her complaints were many and varied. A prior diagnosis of brucellosis could not be confirmed, in part because of previous vaccine therapy. The patient requested the combined streptomycin and sulfadiazine treatment. In keeping with our policy of reserving this treatment for the seriously ill patient, and also because of the dubious diagnosis, her request was refused. She then went elsewhere and obtained the treatment. In January 1948 a five day course of treatment consisting of a total dose of 7 Gm. of streptomycin (1.5 Gm. per day) and 20 Gm. of sulfadiazine was given in another hospital. (This information was furnished by the patient's physician.) On the fourth day of treatment persistent retention of urine developed, and the patient required daily catheterizations. This dysfunction has persisted to the present time, seven months later. Repeated urologic examination here, including cystoscopy, cystometric studies and bladder sensory examinations, have led to the diagnosis of a neurogenic bladder dysfunction. Neurologic examinations, spinal fluid studies, electroencephalograms, tests of visual fields and roentgenograms of the skull and spine yielded no other evidence of disease.

This unusual complication arising shortly after the start of combined streptomycin and sulfonamide therapy and unexplained after intensive investigation of other possible causes, although not necessarily due to the treatment, at least warrants speculation.

Circumoral paresthesia accompanied with objectively demonstrable hypalgesia has been a common occurrence in our patients receiving the combined streptomycin and sulfadiazine treatment. The symptoms and signs usually developed within a few days after treatment was started, even with the relatively small dose of 2 Gm. per day.

### COMMENT

The fatal case of toxic encephalitis reported by Hunnicut and co-workers[2] demonstrates that widespread damage to the central nervous system may be produced by streptomycin. The cases cited here support this thesis. They serve to raise seriously the question of the significance of minor neurologic signs, the paresthesias, which commonly accompany streptomycin therapy. These minor clinical signs of toxicity have previously been largely disregarded. It should be remembered that the lack of definite neurologic signs does not exclude the possibility of insidious or latent damage to many areas of the brain. It is well known that serious neurologic disease may appear many years after the action of an inciting agent. For instance, postencephalitic Parkinsonism may appear long after the acute phase of the disease, and the acute encephalitis may in fact have been so mild as to have been unrecognized at the time. Damage to the so-called silent areas of the brain may escape recognition. These areas, although furnishing a paucity of signs, serve as the highest integrative centers of intelligence.

The usefulness of the combined streptomycin and sulfadiazine treatment in brucellosis was first reported independently by Pulaski and Amspacher[9] and by ourselves.[10] Although we were among the first to use and report this method, we have employed this treatment only in carefully selected cases, in part because of our early recognition of its inherent toxicity. We have recommended[11] that this treatment be reserved for the seriously ill patient.

In our experience with the combined streptomycin and sulfadiazine treatment, the toxic effects on the nervous system have been of such frequency and magnitude that we have seriously considered the likelihood that the combined use of the drugs increases the toxicity as well as the clinical effectiveness of streptomycin, or possibly the nature of the disease may increase the hazards. It should be remarked that our series contained several patients with preexistent central nervous system involvement, a complication which has long been recognized in brucellosis. Both of the severe reactions occurred in patients with long-standing brucellosis with this complication. Milder reactions, however, have occurred in patients without recognizable central nervous system disease.

In patients with a chronic granulomatous disease, the use of a specific treatment may evoke a Herxheimer type of reaction. Granulomatous lesions in brucellosis have been demonstrated to occur throughout the entire brain.[12] In our first 2 cases several factors suggest this as a plausible mechanism for the toxic reaction, namely, the explosive nature of the onset, the short interval between the initiation of treatment and the appearance of the reaction, the peak of the reaction appearing with small total doses of the drug, the prompt production of a clinical picture reminiscent of the symptoms of the initial illness and a sharp but brief rise in temperature during an afebrile period. On the other hand, the frequency of minor neurologic signs, evidencing a widespread toxic action on the central nervous system, makes one question whether these cases are merely exaggerated instances of toxicity in vulnerable subjects.

# TREATMENT OF GLAUCOMA ASSOCIATED WITH IRIDOCYCLITIS

ADOLPH POSNER, M.D.
and
ABRAHAM SCHLOSSMAN, M.D.
New York

The management of ocular hypertension associated with iridocyclitis constitutes one of the most difficult problems in ophthalmology. The accepted dogma is to consider the condition in all such cases as secondary glaucoma and to adopt a more or less standard formula for treatment. Yet, when confronted with a case of iridocyclitis in which ocular hypertension develops, the physician wonders whether to continue with a mydriatic, change to a miotic or resort to surgical treatment. On the other hand, there are instances in which fairly successful miotic treatment was discontinued in favor of treatment with mydriatics, because a few keratic precipitates or cells in the aqueous were discovered.

The vagueness in the approach to this problem is due largely to the manner in which cases of secondary glaucoma have been classified. Of course, the ideal classification would be an etiologic one. There have been occasional reports of cases in which the causative factor has been demonstrated. Weingott[1] reported 3 cases of gonococcic iridocyclitis with glaucoma. However, in the majority of these cases, the cause is unknown. Fralick, Cooper and Armstrong[2] were unable to discover a causative agent in any of their 261 cases of glaucoma associated with iridocyclitis. For the present, a discussion of treatment cannot be based on etiologic considerations. As a matter of fact, it is difficult to find any suitable criteria for a practical classification. Weekers[3] discussed treatment without attempting to classify the cases.

Read before the Section on Ophthalmology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

At best, the criteria for distinguishing between primary and secondary glaucoma are rather arbitrary. At one time there was a tendency to classify as secondary glaucoma any disease in which there occurred pigment deposits on the posterior surface of the cornea.[4] Later, it was shown that such deposits occur in many normal eyes. An opposite point of view was taken by Thiel,[5] who stated that keratic precipitates and posterior synechia may occur in acute glaucoma as a result of the venous stasis. We will revert to this phase of the subject later in the paper. These specific examples from the literature will serve to indicate the complexity of the problem.

For the purpose of treatment, it would be advantageous if the conditions in which glaucoma is associated with iridocyclitis could be divided into therapeutic entities. In the state of present knowledge, however, one cannot hope for a definitive classification even from this point of view. Cattaneo[6] suggested such a classification by dividing his cases into the following three groups:

1. Patients in whom ocular hypertension precedes the iridocyclitis should be treated with miotics followed by ethylmorphine hydrochloride ("dionin") and epinephrine.
2. Patients in whom the two conditions occur simultaneously should be treated with mydriatics and paracentesis.
3. Patients in whom the hypertension occurs in the late stages of iridocyclitis should be treated by operation, such as iridectomy, trephine, sclerectomy or sclerotomy.

The present paper will attempt to clarify further the relationship between the clinical pictures and therapeutic criteria. For this purpose, the following classification is suggested:

1. Iridocyclitis occurring in a person with primary glaucoma
2. Relatively mild cyclitis in which ocular hypertension occurs at the onset or early in the course of the disease
    (*a*) Syndrome of recurrent glaucomatocyclitic crises
    (*b*) Iridocyclitis without posterior synechiae (or with old synechiae) associated with the early appearance of ocular hypertension
3. True secondary glaucoma resulting from iridocyclitis
    (*a*) Early: associated with plasmoid aqueous, active iridocyclitis and fresh posterior synechiae
    (*b*) Late: associated with structural changes in the filtration chanels or with long-standing uveitis

### 1. IRIDOCYCLITIS IN PRIMARY GLAUCOMA

Rarely, iridocyclitis may occur in association with primary glaucoma. Out of 12,000 patients, 3.1 per cent suffered from primary glaucoma, while 0.9 per cent had iridocyclitis. The expected frequency of coincidental occurrence of the two diseases in the same patient would thus be 0.028 per cent, or about 3 cases out of 12,000. Actually, 2 such cases were observed in this series. One of these will serve as an example.

A. M., a 67 year old housewife, was first seen in 1933 with acute iridocyclitis of the left eye, which was followed on the next day by a similar inflammation of the right eye. She improved with atropine and scopolamine therapy, but the ocular tension remained elevated. The eyes became white, and the patient did not return to the office until two years later. At this time, she had tension of 65 mm. in both eyes and deep cupping of both disks. The right field was normal, but the left showed pronounced nasal contraction. The picture was that of chronic simple glaucoma without symptoms. Bilateral Elliot trephine operations normalized the tension, and her status had remained relatively unchanged to the time of writing.

The condition in this case was treated at first as secondary glaucoma; only the subsequent course revealed the true nature of the disease. Fortunately, the use of atropine and scopolamine in this case did not have any disastrous effects. Conditions of this type, however, should be treated with caution. At first, treatment with the miotic is discontinued. If the anterior chamber has a narrow angle, phenylephrine hydrochloride ("neo-synephrine hydrochloride"), 10 per cent, may be used to break up or prevent synechiae. In the presence of a wide angle, a filtering bleb or an iridectomy coloboma, homatropine may be used cautiously.

While the low incidence of these cases makes them less important clinically, they serve to emphasize the fact that the presence of iridocyclitis does not automatically stamp a case of glaucoma as secondary.

### 2. MILD CYCLITIS WITH GLAUCOMA

One occasionally encounters a condition which, at first, seems to have all the features of primary glaucoma. Within a few days, a few cells are seen in the aqueous or a few keratic precipitates are discovered. According to the accepted teaching, the diagnosis should then be changed to secondary glaucoma. In the mind of the average ophthalmologist, it is almost mandatory to change to treatment with mydriatics. Yet, if the tension has been fairly well controlled or, on the other hand, if it is very high, he hesitates to use atropine or homatropine. It has been our experience that this mental reservation is justified.

From physiologic considerations, it seems plausible that the presence of a large number of cellular elements, fibrin and other plasma proteins may cause a rise in the intraocular pressure, by mechanical blockage of the filtration channels, by increasing the colloid osmotic pressure of the aqueous or by a combination of both factors. However, these mechanisms cannot be invoked to explain a tension of 70 to 90 mm. when only a few keratic precipitates or cells are present, in the absence of an abnormal aqueous ray. The mechanism responsible for the rise in intraocular pressure in these cases is undoubtedly different from that causing glaucoma secondary to active iridocyclitis.

*Syndrome of Recurrent Glaucomatocyclitic Crises*.—This condition was described as a clinical entity in a previous report.[7] It is characterized by recurrent attacks of unilateral glaucoma associated with mild cyclitic signs. The patient complains of vague ocular discomfort, but no real pain. The visual acuity is usually normal, even at the height of the attack. The eye shows little or no evidence of congestion or ciliary injection, but there may be a slight scleral flush if the tension is very high. A few cells and keratic precipitates may be present at the first examination, or they may appear a day or two later. The ophthalmologist is amazed to find an ocular tension of 60 mm. or over, and in some cases as high as 90. There may be a history of one or more previous attacks. We reported 9 cases of this type. The chamber angle was moderately narrow in one half of the patients examined with the gonioscope and wide in the other half. None of the patients showed peripheral anterior synechiae. Without treatment, the tension returns to normal within one to three weeks, although there may be spontaneous fluctuations during this time. The keratic precipitates disappear within a month after subsidence of hypertension. The visual field remains unchanged over several years, despite recurrent attacks. Widened angioscotomas may be noted during the attack. The condition is frequently associated with allergy and essential hypertension. If heterochromia is present, the eye with the lighter-colored iris is affected. The other eye remains normal. The following case history illustrates the essential features of this syndrome.

In 1927 R. M., a 52 year old housewife, began to have attacks of edematous swellings in different parts of the right side of the face and neck, associated with headache and misty vision of the right eye. An ophthalmologist found the tension of this eye to be 70 mm. Schiotz and prescribed pilocarpine. The following day the tension was normal. She continued to use low concentrations of pilocarpine, even though her tension remained normal. In June 1933, she complained of blurred vision in the right eye of two days' duration. The eye was white. The tension was 45 mm., and a few fresh keratic precipitates were present. She was given homatropine, and the tension subsided within three days. No foci of infection were found. The precipitates disappeared within three weeks. In February 1934, during a similar episode, she was again given homatropine and subsidence of the attack followed within a few days. During the following year, in spite of the prophylactic use of pilocarpine, another attack occurred and subsided with pilocarpine therapy.

She was followed in this office since 1942 at monthly intervals by Dr. Schoenberg and later by us and suffered no recurrences until November 1947, when she experienced some blurring of vision and halos of the right eye. The tension was 66 mm. in the right eye and 23 mm. in the left. The vision of the right eye was 20/25 with correction. Pilocarpine, 1 per cent, increased the blurring of vision and failed to reduce the tension. She used 0.25 per cent pilocarpine twice a day and felt relatively comfortable. It was not until the third day that a few precipitates appeared on the posterior surface of the cornea. The tension fluctuated between 36 and 90 mm., until two weeks after the onset, when it dropped to 15 mm. (7 mm. less than the unaffected eye). As of the time of writing, the tension had remained normal. The keratic precipitates disappeared within a month. The field showed widened angioscotomas at the height of the attack but returned to normal. A pupillogram, made by Dr. Otto Lowenstein in March 1947, showed a bilateral curve similar to that in primary glaucoma. Gonioscopic study showed both chamber angles to be open and wide even during the attack. Patient had mild essential hypertension.

In treating these patients, one should bear in mind that the attack is self limited. If possible, it may be wise to follow at least one attack without treatment or with placebo treatment. Since this syndrome may be regarded, in a sense, as a form of glaucoma intermediate between primary and secondary, it is best to avoid both strong miotics and strong mydriatics, particularly eserine, neostigmine, di-isopropyl fluorophosphite (DFP) and atropine, no matter how high the tension rises. We have found that pilocarpine in concentrations of 0.5 to 2 per cent is usually effective in lowering the tension, at least temporarily. Although it may cause myopia, it does not cause any discomfort. Epinephrine bitartrate, 2 per cent, and "neo-synephrine hydrochloride," 10 per cent, may also reduce the tension, even though the pupil becomes dilated. Eserine and neostigmine may give rise to congestion, pain and even elevation of tension. DFP has not been used in this group, but one would expect similar effects from it. Since the disease is self limited and causes no permanent impairment of the visual functions, surgical treatment is not indicated.

*Iridocyclitis Without Posterior Synechiae Associated with Early Glaucoma.*—Patients with iridocylitis without posterior synechiae associated with early glaucoma show a large number of keratic precipitates and slight ciliary injection, observations which indicate the presence of active cyclitis. In some cases, the precipitates are so numerous that the entire posterior cornea is studded with them. They do not form posterior synechiae during the course of the attack. The ocular hypertension occurs concomitantly with, or early in the course of, the cyclitis. Both the hypertension and the keratic precipitates persist longer than in the syndrome of glaucomatocyclitic crises. Both eyes may be affected.

The patients should be treated with pilocarpine up to 2 per cent alternated with phenylephrine hydrochloride, 2.5 per cent or 10 per cent. The latter drug has a threefold action: it alleviates congestion, dilates the pupil and helps to lower the tension. The most important criterion in the treatment is the presence or absence of posterior synechiae. Pilocarpine may be used safely as long as there is no tendency toward the formation of posterior synechiae. For this reason, it is advisable to study the eye frequently with phenylephrine hydrochloride mydriasis. If an old synechia is noted at the first examination, it need not influence the course of treatment. It is well known that these patients tolerate a moderate elevation of tension, up to 40 or 45 mm., for some time without losing field. Even if such elevation persists for several weeks, the physician need not be alarmed. If the tension is higher and does not respond to medication, sorbitol may be used intravenously or paracentesis performed.

These cases of relatively mild cyclitis with glaucoma, and particularly the syndrome of glaucomatocyclitic crises, give the impression that there is no direct causal relationship between the cyclitic manifestations and the glaucoma. Even if one believes that both the cyclitis and ocular hypertension have the same causative factor, one still does not know what this factor is. In some glaucomatocyclitic crises there are no keratic precipitates or cells for the first few days, and in others visible signs of cyclitis are absent throughout the attack. The thought cannot be dismissed that some cases of so-called primary glaucoma may be related to this group. Evidently, the lack of a sharp line of demarcation has led Thiel to include under primary glaucoma some conditions with a few keratic precipitates. After all, the vascular phase of congestive glaucoma is, in part, an expression of an irritability of the ciliary body, as demonstrated by the sensitivity to strong miotics. The discovery of a few keratic precipitates should not, per se, lead to a radical change in the course of treatment.

### 3. TRUE SECONDARY GLAUCOMA

*Early Appearance of Ocular Hypertension.*—This group is made up of cases in which glaucoma may be assumed to be a direct result of the iridocyclitis. In cases of active iridocyclitis, the hypertension may be due either to the change in osmotic pressure of the aqueous or to mechanical blockage. The treatment should be directed to the uveitis. Mydriatics are useful either to break up the synechiae or to prevent new ones from forming during the acute phase. Atropine may be combined or alternated with 10 per cent phenylephrine hydrochloride to obtain maximum dilatation. Sometimes the tension will drop as soon as the synechiae have been freed. If the tension remains high, it is advisable to discontinue the atropine and to rely on milder mydriatics. Daily paracentesis may be helpful in keeping the tension down until the iridocyclitis is controlled. Retrobulbar injection of alcohol has been recommended by Weekers.[3]

Systemic treatment is directed toward the causation when the latter is known. Salicylates and fever therapy are useful in combating uveitis. Sorbitol may help to reduce the hypertension.

*Late Appearance of Ocular Hypertension.*—In this group may be included all cases of secondary glaucoma due to structural changes in the eye in which the uveitis is either healed or relatively quiescent. Since the hypertension constitutes the more important therapeutic problem, mild miotics and intravenous therapy may be employed. Surgical intervention is necessary in a large proportion of the patients. Iridectomy, iridencleisis or cyclodialysis are operations which have been used. The type of operation depends on the individual preference of the ophthalmologist and on the clinical characteristics of the specific case.

Certain cases of secondary glaucoma following cataract operation are due to sluggish uveitis. Two years ago, at the American Medical Association Convention, Chandler and Johnson[8] called attention to the mechanism involved in this condition. They advocated mydriatics, discission, transfixion of the iris and iridectomy.

### SUMMARY

For the purpose of treatment, the glaucoma associated with iridocyclitis is divided into three types. Emphasis is placed on the second type, which includes the syndrome of glaucomatocyclitic crises and other conditions in which posterior synechiae are not formed. Treatment in these cases differs from the conventional formula for secondary glaucoma. The use of mild miotics in combination with phenylephrine hydrochloride ("neo-synephrine hydrochloride") is advocated.

## ABSTRACT OF DISCUSSION

**Dr. Paul A. Chandler**, Boston: In regard to the specific types discussed by the authors, the first group consists in iridocyclitis occurring in a person with primary glaucoma. In the case cited the condition might well be classified residual glaucoma after subsidence of the uveitis. As the authors stated, iritis or uveitis occurring in a patient with known primary glaucoma is extremely rare, and few of us have had the opportunity of treating many of these patients. On the basis of experience with a single case, I feel that the glaucoma may be disregarded and atropine employed for the duration of the inflammation and then miotic therapy may be resumed. The syndrome designated as glaucomatocyclitic crises is an interesting one. The evidence of cyclitis is always mild. Even in the presence of a wide angle one sees an acute rise in tension in every way similar to that of primary acute glaucoma. In the authors' experience the tension fell with such widely different types of treatment as dilatation of the pupil, constriction of the pupil and the use of epinephrine. The fall in tension also occurred spontaneously. I have had a similar experience after a single paracentesis; tension may remain normal for weeks without further treatment. One wonders, therefore, whether the tension falls because of or in spite of treatment. When one has observed such a case long enough to be certain it is of this type, it should be considered as one of primary glaucoma and treatment planned accordingly, disregarding the keratitic precipitates and cells entirely. In chronic low grade iridocyclitis without posterior synechiae, the glaucoma may be mild or severe or may not occur at all. It is difficult to make a rule for treatment in these cases. The most effective treatment for the glaucoma is often arrived at by trial and error. It is perhaps wise to start off with atropine, with or without epinephrine, and finally miotics if necessary. In long-standing cases which show progressive cupping of the disk and loss of field, a trephining operation is justified and may be effective. The authors refer to iridocyclitis with posterior synechiae complicated by glaucoma. This may be a most difficult type to deal with. Sympathetic uveitis complicated by glaucoma is the worst example of this type. Dilatation of the pupil is essential in these cases. The epinephrine compounds may have great value, and, finally, palliative surgical treatment may have to be employed. The authors suggest conservatism in surgical procedures in these cases, and I am in most hearty agreement. Repeated paracentesis certainly favors the development of peripheral anterior synechiae. It is not the level of the tension per se, but what it does to a particular eye, that is important. One may be conservative as long as the function of the eye is not impaired by the tension. The final type discussed, residual glaucoma after the uveitis has quieted down, is to all intents and purposes primary glaucoma. In this type of case I have had better success with iridencleisis combined with sclerectomy than with other types of operation.

**Dr. Albert D. Ruedemann**, Detroit: Dr. Posner and Dr. Schlossman have drawn attention to the therapeutic differentiation in the treatment of the glaucomas. They stress the point that causative factors have not been found in the production of glaucoma. I would like to call attention to this, because that refers to effect and not cause. The cause of glaucoma has not been found, simply because ophthalmologists do not know how to look for it. Ophthalmologists refer patients to medical physicians who know nothing about the cause of glaucoma or what to look for. Therefore, we, as ophthalmologists, will have to change our method of investigation of the cause of glaucoma and search for the minimal pathologic changes in the other parts of the body, as well as in the eye. With the advent of gonioscopy and the further study by microscopy of changes in the eye, it would be advisable to investigate the rest of the host from the same point of view instead of trying to find the changes in roentgenograms of the chest and similar lesions. Minor changes in the blood and microscopic changes in the general system must be investigated. The therapeutic differentiation, as stressed by Dr. Schlossman, brings out one important point: the prolonged use of any miotic may in itself cause trouble, because the sensitivity to the drug used will develop in the patient. One should search for posterior synechiae; the pupil should be dilated with epinephrine, and periodically the eye should be allowed to recover from the prolonged use of miotics. In cyclitis, with and without glaucoma, it might be possible that there would be an irritating aqueous which, on exposure to light, undergoes a photochemical change, and that produces the irritating cyclitis. The use of any of the stronger miotics in some cases of glaucoma not only does not help prevent further increase in tension but will add to the increase in tension by the secondary reaction to the drug. The numerous drugs mentioned would make it advisable to know that there is a decided sensitivity to drugs in the eye, and, unless one is aware of this to start with, one not only does not prevent further rise in tension but may increase it.

**Dr. Harvey Thorpe**, Pittsburgh: I, too, have seen numerous cases of secondary glaucoma due to cyclitis. I was impressed, however, with the fact that in cases of uveoparotid syndrome, which is now considered to be sarcoidosis, there is a greater frequency of secondary glaucoma than in cases of subacute iridocyclitis. In the patients with milder forms of sarcoidosis of the eye there are often few keratic precipitates visible on the endothelium. On the other hand, if the patients are examined gonioscopically, one observes a greater incidence of keratic precipitates in the chamber angle than one would be led to suspect by the regular examination. Therefore, one might consider these cases from the etiologic point of view in searching for sarcoidosis, which has definite clinical pathologic manifestations. Drs. Posner and Schlossman, too, have pointed out that one must consider the possibility of the occurrence of cyclitis in a glaucoma host. In some cases of sarcoidosis a rise in intraocular tension subsided spontaneously, in spite of the fact that homatropine, pilocarpine and 10 per cent phenylephrine hydrochloride ("neo-synephrine hydrochloride") seemed to exert no influence. On the other hand, 2 of the patients with uncontrollable conditions required a wide basal iridectomy. I recall 1 case of bilateral glaucoma with subacute cyclitis in which the tension returned to normal after three weeks, although it had failed to react favorably to either miotics or mydriatics. This, too, was a case of uveoparotid fever, or sarcoidosis, as this syndrome is now understood. The patient, a woman of 20, had facial paralysis on the left side, followed by facial palsy on the other side about four weeks later. This was associated with enlargement of the parotid and maxillary glands, enlargement of the sternal shadow observed roentgenographically and some of the other symptoms associated with sarcoidosis. Her mother had narrow angle glaucoma in one eye associated with an intumescent lens. Of course, all factors bearing on these cases, including etiologic factors, must be considered when one thinks of diagnosis and therapy. I am sure that Drs. Posner and Schlossman have considered these. In some of my cases, foreign protein therapy, in the form of milk injections and typhoid injections, have been of extreme value.

---

[8] Chandler, P. A., and Johnson, C. C.: A Neglected Cause of Secondary Glaucoma in Eyes in Which the Lens Is Absent or Subluxated, Arch. Ophth. **37**: 740-771 (June) 1947.

Dr. Conrad Berens, New York: I would like to ask two questions: First, what has been the experience of Dr. Posner and Dr. Schlossman in the management of cases of allergic disease? Recently, I had several patients who were allergic to all miotics. I have recently tried giving them "antistin" (2-[N-phenyl-N-benzyl-aminoethyl] imidazotin) or one of the other antihistaminic preparations along with the miotic. The second question pertains to the management of patients who have sympathetic disease. I am fortunate in having seen such a patient, who had tension varying from 45 to 70. Everything had been tried before I saw the patient, who was referred for consultation. There was no anterior chamber to speak of; I could not get fluid out even by aspiration. Realizing the cataract would have to come out some day, I performed an iridectomy, although I had never been successful with this procedure previously. When this did not control the tension, retrobulbar injections of alcohol were made. I do not hesitate to use 30 per cent alcohol, as first suggested to me by Dr. Edward Hartmann in 1940. It has been a helpful procedure in cases of uveitis with secondary tension. In patients whose vision is poor I use stronger solutions, that is, up to 50 and 70 per cent alcohol. For the patient I speak of, the tension remained elevated. Aspiration was again attempted, and when no fluid could be withdrawn I tried cycloelectrolysis. I have been using this procedure for two and a half years. Using a 2 mm. needle, my co-workers and I gave fifty punctures over the lower half of the globe, applying 5 milliamperes of current for five seconds. Surprisingly enough, there was practically no reaction. At the end of a week the patient returned to his home. The other day I saw the oculist who referred the patient. He said that the patient's tension was remaining down. This procedure should be given consideration. So far, we have observed less secondary congestion postoperatively than we had observed with cyclodiathermy. I have used this procedure in about 40 instances to date, although only twice in patients with cyclitis. One patient had a blind eye, which I wished to preserve. The procedure was only partially successful, and the tension remained about 40. Cycloelectrolysis is something one may consider when everything else fails.

Dr. Everett L. Goar, Houston, Texas: I am surprised that no one has brought up the question of secondary glaucoma due to iridocyclitis following cataract extraction, especially the capsulotomy type. This is one of the most troublesome types to treat, as it is no doubt often due to sensitivity to lens protein. One of the first signs of increased intraocular pressure is bedewing of the corneal epithelium, as seen by the biomicroscope in retroillumination. This not infrequently follows discission of a secondary membrane. I can recall producing uveitis and glaucoma in both eyes of a patient by discission and then treating one eye with a mydriatic and the other with a miotic.

Dr. Posner: I want to express my thanks to the discussers for the interest they have shown in this paper, which, after all, is only a modest attempt at analysis and classification of glaucoma associated with iridocyclitis. I can answer Dr. Berens' first question in regard to "antistin" (2-[N-phenyl-N-benzyl-aminomethyl] imidazotin). I have 1 patient, a physician, who is subject to frequent recurrences of glaucomatocyclitic crises. He has tried every antihistaminic drug, including "antistin," and apparently it has no effect. I cannot hope to comment on all the other discussions in the limited time. I would like to reemphasize the fact that, clinically, secondary glaucoma is not a single entity and that one must modify treatment according to the clinical behavior of the disease. I believe that a more careful analysis and study of glaucoma associated with mild cyclitis, which forms a borderline between primary and secondary glaucoma, may help in time to shed some light on the pathogenesis both of glaucoma and of cyclitis.

# TREATMENT OF THE FAT AND THE LEAN

CLIFFORD F. GASTINEAU, M.D.
EDWARD H. RYNEARSON, M.D.
and
ALICE KARSLAKE IRMISCH, M.S.
*Rochester, Minn.*

The extreme variation which body weight may undergo is indeed remarkable. There is a report, probably true, of a man weighing over 1,000 pounds (453.5 Kg.), while a subject weighing 779 pounds (353.3 Kg.) has been studied by competent observers.[1] At the other extreme, a 30 year old woman has recently been observed at the Mayo Clinic who weighed 44 pounds (20 Kg.) and was 5 feet 3.5 inches (161.3 cm.) in height.

While such spectacular deviations attract interest, lesser grades of underweight and overweight are of great importance in the health of the individual and are of much greater importance from the standpoint of public health than are sideshow freaks. In the latter half of life even moderate obesity is dangerous, and it has been shown that between the ages of 45 and 50 years 25 pounds (11.3 Kg.) of excess weight results in an increase of 25 per cent in mortality.[2] Greater degrees of obesity are a correspondingly greater hazard to life and health. Obesity has been found to be associated with an increased incidence of hypertension, diabetes, cancer, heart disease, nephritis, atherosclerosis, toxemia of pregnancy, cirrhosis of the liver, emphysema and varicose veins;[3] it seems certain that correction or prevention of obesity would greatly diminish the incidence of these degenerative diseases for which we often have little specific therapy.

Underweight is less strikingly related to disease and increased mortality, and yet it has been demonstrated

that the underweight person under the age of 30 has an increased susceptibility to tuberculosis.[3] It has been said that the greatest life expectancy occurs in those persons who are slightly overweight up to the age of 30, of average weight from ages 30 to 40 and distinctly underweight thereafter.[4]

For all these reasons it would be an important advance in the health of the nation if all physicians were alert to the dangers of overweight and if they applied a missionary zeal to the correction of this condition.

## ETIOLOGIC FACTORS

Leanness and obesity have a common cause: a disproportion between caloric intake and caloric requirement. If the person eats more than he requires to maintain normal weight he becomes obese; if he eats less, he becomes thin.

*Psychologic Aspects.*—The causes for undereating and overeating in the presence of an adequate supply of food are to some extent conjectural, but one can be certain that emotions, training and habit exert a considerable influence.

If mother prides herself on setting a good table, if dad eats heartily and with obvious enjoyment, if the household attitude and feeling is that good food in generous quantities is the end and purpose of life, it is not surprising that an entire family may become obese without the mediation of genes. Thus, imitation of elders and attitudes acquired in childhood may govern eating habits in later life.[5] In addition to variations in body weight caused by simple training and habit, there are those caused by the neuroses and psychoses. Investigations by a number of psychiatrists of the lean and the fat have suggested a strikingly high incidence of psychologic aberrations,[6] and yet the reason is not always apparent why a certain conflict or anxiety may cause polyphagia in one person, anorexia in another and have no effect on the appetite of a third.[7] The apparently increased incidence of neuroses in association with obesity or leanness may be open to some question, since most such investigations have not included psychiatric studies of persons of normal weight for control purposes.

*The Hypothalamus.*—We have indicated how the cerebral cortex may play an important role in control of weight through the effect of emotions and training on appetite. More primitive portions of the nervous system undoubtedly exert some influence on appetite on a more automatic level, however.

In recent years experiments on animals have shown that destruction of certain nuclei in the posterior portions of the hypothalamus will cause a voracious appetite, so that the intake of food is limited only by the capacity of the gastrointestinal tract. Extreme obesity quickly and invariably develops, but if the animal is fed amounts equivalent to those consumed by control animals, the weight remains normal.[8] Such experiments strengthen the earlier hypothesis of Wilder[9] that the diencephalon contains a center for the control of appetite, and one might infer that a "constitutional tendency" toward leanness or obesity might depend on the sort of hypothalamus that one happens to inherit.

These experiments also suggest that the obesity which Fröhlich described in 1909 as the result of an intracranial lesion was the consequence of hypothalamic injury.[10] The terms "Fröhlich's syndrome" and "adiposogenital dystrophy" both have been applied frequently to obese but healthy adolescent boys whose genitals are partly obscured by fat. When these terms are used to describe the appearance of such persons, it carries the unfortunate implication of some fundamental endocrinologic or intracranial disorder. One might postulate a temporary derangement of hypothalamic function without demonstrable structural change to explain the clinical appearance of such boys, but no convincing evidence for this exists. For these reasons we would restrict the terms "Fröhlich's syndrome" and "adiposogenital dystrophy" to those obese, sexually immature males who are definitely older than the age of normal puberty and who have additional evidence of a lesion involving the region of the hypothalamus and hypophysis.

*Endocrine Factors.*—In the past, endocrine disorders have been the favorite scapegoats on which to place the blame for both obesity and leanness, and there have been attempts to diagnose many varities of endocrinopathy by slight variations in the distribution of body fat. Actually, endocrine disorders are rarely a cause of either pronounced obesity or leanness. Distribution of fat is of little diagnostic significance except in the instances of Cushing's syndrome and progressive lipodystrophy.

Lipodystrophy is a rare nonendocrine condition characterized by the unequal distribution of fat, large masses appearing in some portions of the body and atrophy of the subcutaneous tissues in others.

Cushing's syndrome is now considered to be a syndrome of hyperfunction of the adrenal cortex, and it is usually but not invariably accompanied by an increase in weight. The appearance of such a patient is rather distinctive, however, and it is only in these exceedingly rare instances that obesity is the consequence of adrenal cortical dysfunction.

The frequent association of obesity with functioning islet cell tumors of the pancreas is the result of the increased intake of food which these patients find necessary to relieve attacks of hypoglycemia. Anxiety may at times cause symptoms of hypoglycemia which are associated with moderate lowering of the concentration of blood sugar in the absence of an islet cell tumor; however, there is no such consistent association of obesity with this type of functional hypoglycemia as there is with the hypoglycemia resulting from islet cell tumor.

Hypothyroidism has been blamed frequently for obesity, but no conclusive evidence for this has been advanced. Plummer[11] in a study of spontaneous myxedema found no tendency toward obesity; furthermore, the basal metabolic rate in obesity is ordinarily found to lie within quite normal limits.[12] There is no conclusive evidence that obesity may result from lesions or dysfunction of the hypophysis, although almost every possible combination of hyperfunction or hypofunction of any or all of the three lobes of this gland has been suggested as a cause for obesity. Although hypogonadism has been observed to cause obesity consistently in castrated animals, no such certain relationship appears to exist in human beings. The evidence for "pineal obesity" is equivocal, and it is entirely possible that the association of pineal tumor and obesity may be the result of hypothalamic damage. Dercum's disease or adiposis dolorosa has not been established as an entity, and the term should be discarded.

When confronted with a patient weighing 60 to 70 per cent of his ideal weight, with no cause for his emaciation apparent, one should think immediately of anorexia nervosa (the figure). This syndrome is characterized by the following sequence of events. The patient is usually a woman below the age of 30 in whom there develops an aversion, of psychologic origin, to food, the exact mechanism of which often is not clear. This aversion to food leads to slow starvation and emaciation, which lead in turn to a functional hypopituitarism which is reversible by means of dietary therapy. These patients display a surprisingly great amount of physical and mental activity in spite of advanced emaciation. A low basal metabolic rate, an appearance of somewhat accelerated aging, amenorrhea, pallor and a tendency toward a growth of fine hair over the body and face are among the findings.[13]

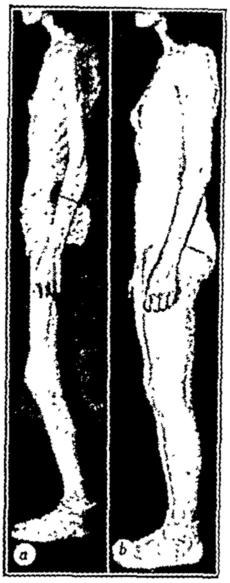

Fig. 1.—A characteristic case of anorexia nervosa. This 20 year old woman made a good response to feeding. (*a*) Before treatment, Oct. 23, 1944; weight 61 pounds (27.7 Kg.). (*b*) After treatment, June 14, 1946; weight 111 pounds (50.3 Kg.). (From Berkman, J. M.; Weir, J. F., and Kepler, E. J.: Clinical Observations on Starvation Edema, Serum Protein and the Effect of Forced Feeding in Anorexia Nervosa, Gastroenterology **9**: 357-390 (Oct.) 1947.

In hypopituitarism secondary to an organic lesion there is rarely loss of weight comparable to that observed in anorexia nervosa; Sheehan and Murdoch[14] in their extensive study of post-partum pituitary insufficiency failed to record emaciation as a symptom. The diagnostic term "Simmonds' disease" requires a clarification that is beyond the scope of this paper; it is sufficient to say that pituitary insufficiency rarely is found to be the cause of emaciation.

*Metabolism of Energy.*—Many abnormalities of the metabolism of energy have been postulated as causes of both obesity and leanness, but none have been convincingly demonstrated. A widely held but erroneous opinion is that the gastrointestinal tract of obese person absorbs a greater proportion of the food passing through it than does that of a normal person.[2] Similarly, it is commonly but wrongly believed that thin persons are thin because they fail to absorb food normally.[15] It is only in those patients with sprue or similar syndromes that inadequate absorption may be assumed to be a cause of leanness.

*Constitutional Factors.*—The possibility of an inherited tendency to obesity is suggested by observations of strains of obese yellow rats in which obesity tends to be inherited in a dominant manner.[16] It is generally agreed that obesity[17] and leanness each have a tendency to occur with greater frequency in certain families than in others. But it is difficult to hazard a guess whether genes or environment exerts the greater influence on eating habits. It is likely, however, that in some persons inheritance is of the greater importance, while in others, or in the same persons under different circumstances, psychologic and environmental influences are the stronger.

It is a common rationalization of obese patients to say that they cannot help being fat "because my parents were big people," and they fear that to reduce to a normal weight would be to endanger their health, since they were "meant to be fat." Such patients should be told emphatically that their fat is no less dangerous to them than to those without a hereditary tendency to obesity and that diet will be no less efficacious in their cases.

Many other hypotheses as to the cause of obesity and leanness have been advanced, but they are not well enough founded to be considered in this brief article.

### CONTRAINDICATIONS TO LOW CALORIC DIETS

Contraindications to reduction are few. It is usually best, however, to postpone reduction in patients who have peptic ulcer or tuberculosis until the activity of the process is abated, at which time a diet of 1,200 to 1,500 calories adapted to the needs of the patient may be prescribed. Hypertension and old age certainly are not contraindications to reduction but rather are urgent reasons for it.

### THERAPY

*Diet.*—The treatment for both obesity and leanness is essentially the same: a diet and such psychotherapy as is necessary to cause the patient to adhere to it.

When the amount of weight to be lost is large or when a rapid loss is important, diets of 600 to 1,000 calories, in which the portions of food are weighed, are usually prescribed. When a less rapid rate of loss is required, diets of 1,000 to 1,500 calories, in which the food is measured by volume, may be used. In tables 1 and 2 are given 1,000 calory and 3,000 calory diets for which the size of the portions of food is stated in terms of both weight and volume. Reduction diets in greater variety are given elsewhere.[18] Although the weighing of food seems a difficult and tedious procedure, it is actually a rather simple task if a scale with a movable face, such as that designed for the use of diabetics, is utilized. The greater accuracy attained when the food is weighed usually justifies the somewhat greater effort because the actual caloric intake frequently will be 200 or more calories in excess of that prescribed if the patient measures his food by volume.

TABLE 1.—*Day's Allowance of Food*

| 1,000 Calory Diet | 3,000 Calory Diet |
|---|---|
| 1. Lean meat, fish, fowl, dry cottage cheese, 150 Gm. (5 oz.), and 1 egg. Must be free from fat, cooked without fat (no gravy) | Any meat, fish, fowl, cheese, 150 Gm. (5 oz.), and 1 egg. Cooked in any manner |
| 2. Skim milk or buttermilk, 480 Gm. (1 pint) | Half milk and half 20% cream, 720 Gm. (¾ quart). May be plain or flavored |
| 3. Bread or plain rolls, 60 Gm. (2-3 slices) | Bread, rolls, pancakes, hot breads, 120 Gm. (4-6 slices) |
| 4. Cereal, none | Cereal, 15 Gm. dry (½ cup as served) |
| 5. Starchy foods such as potato, beans (dried or lima), corn, hominy, macaroni, noodles, rice, spaghetti, none | Starchy foods (see 1,000 calory diet), 200 Gm. (1 cup) |
| 6. Vegetables (except above), 400 Gm. (2 cups). Canned, cooked, frozen or raw | Vegetables, any, 300 Gm. (1½ cups). Canned, cooked, dried, frozen or raw |
| 7. Fruits (see list below), 3 servings including 1 of citrus fruit or juice | Fruits, any. At least 100 Gm. (½ cup) citrus fruit or juice plus any other canned, cooked, dried, frozen or raw |
| 8. Desserts, none except saccharin-sweetened gelatin dessert, rennet dessert or custard made with skim milk | Desserts, 200 Gm. (2 servings) of cake, cookies, ice cream, pie, pastry, pudding |
| 9. Sweets, none except saccharin | Sweets, at least 3 tbsp. sugar, jam or jelly |
| 10. Soups, none except clear broth or soup made from vegetable or skim milk allowance | Any thickened or cream soup, 100-200 Gm. (½-1 cup |
| 11. Fat (butter, margarine, mayonnaise or oil), 15 Gm. (1 level tbsp.) and 20% cream, 30 Gm. (2 tbsp.) | Fat (butter, margarine, mayonnaise or oil including that used in cooking), 75 Gm. (5 level tbsp.), and 20% cream, 75 Gm. (⅓ cup) in addition to 360 Gm. in the milk |
| 12. Miscellaneous (black coffee, clear tea, herbs, lemon juice, salt, spices, vinegar), as desired | Miscellaneous (coffee, tea, carbonated beverages, herbs, salt, spices, vinegar), in moderation |

Servings of Fruit Allowed on 1,000 Calory Diet

| Fresh | Water-Packed Canned |
|---|---|
| ½ apple | ½ cup apple sauce |
| 1 apricot | 4 halves apricots |
| ½ banana, small | 1 cup blackberries |
| ½ cup blackberries | ½ cup blueberries |
| ⅓ cup blueberries | 1 cup cherries, red or white |
| ½ cup cranberries | ½ cup cherries, black |
| ⅓ cup currants | ½ cup fruit salad |
| ½ grapefruit | ½ cup grapefruit juice |
| ½ cup grapefruit juice | ⅓ cup Kadota figs |
| ⅙ honeydew melon | 1 cup loganberries |
| ⅓ cup huckleberries | ½ cup orange juice |
| 1 lemon | 1 cup peaches |
| 2 limes | 2 halves pear |
| 1 orange, medium | 2 rings pineapple |
| ½ cup orange juice | ½ cup pineapple juice |
| 1 peach | 2 plums |
| ½ pear | 1 cup raspberries |
| 2 rings pineapple | 1 cup strawberries |
| 1 plum | ½ cup white grapes |
| ⅓ cup raspberries | |
| 1 cup rhubarb | |
| ½ cup strawberries | |
| ¼ slice watermelon | |

The success of dietary therapy is dependent in large part on the patient's knowledge of his diet, which in turn depends on painstaking and careful instruction. Such instruction provides the additional benefit of impressing the patient with the importance of diet.

Many regimens are unsuccessful because the doctor gives his patient a printed diet list with little or no explanation and instruction. Menus which are so limited as to be difficult to obtain either at home or in a restaurant are further reasons for failure. Diets given in tables 1 and 2 permit an almost infinite choice of foods, thereby avoiding monotony and some of the difficulties associated with many diets. It is desirable in the course of instruction to have the patient write out several possible menus adapting the diet to his racial and individual preferences, his economic level and his daily program of work.

TABLE 2.—*Examples of 1,000 Calory and 3,000 Calory Diets*

| | | 1,000 Calory Diet | | 3,000 Calory Diet | |
|---|---|---|---|---|---|
| Foods Allowed | Sample Menu | Wt., Gm. | Approximate Measure (Volume) | Wt., Gm. | Approximate Measure (Volume) |
| | | BREAKFAST | | | |
| Fruit, citrus | Grapefruit | 100 | ½ medium | 100 | ½ medium |
| Cereal | Whole grain cereal | ... | ............ | 15 | ½ cup |
| Egg | Egg, soft cooked | 50 | 1 | 50 | 1 |
| Bacon | Bacon | ... | ............ | 15 | 2 strips |
| Bread | Whole wheat toast | 20 | 1 slice | 40 | 2 slices |
| Butter | Butter | 5 | 1 tsp. | 14 | 2 squares |
| Beverage | Coffee | ... | 1 cup | ... | 1 cup |
| Cream, 20% | Cream | 30 | 2 tbsp. | 75 | ⅓ cup |
| Sugar | Sugar | ... | ............ | 15 | 1 tbsp. |
| Jelly | Jelly | ... | ............ | 20 | 1 tsp. |
| | | DINNER | | | |
| Soup | Cream of potato soup | ... | ............ | 100 | ½ cup |
| Meat or substitute | Roast beef | 75 | 2½ oz. | 60 | 2 oz. |
| Potato or substitute | Mashed potato, gravy | ... | ............ | 100 | ½ cup |
| Vegetable | New cabbage | 100 | ½ cup | 75 | ⅓ cup |
| Salad | Sliced tomato | 100 | 1 medium | 75 | ½ large |
| Salad dressing | Mayonnaise | ... | ............ | 15 | 1 tbsp. |
| Fruit (list, table 1) | Sliced orange | 100 | 1 medium | ... | ............ |
| Dessert | Vanilla ice cream | ... | ............ | 70 | ⅓ cup |

To insure inclusion of these essential factors, the physician should prescribe a multivitamin capsule to be taken daily by the reducing patient. Salt and water may be taken in whatever quantities the patient desires.

Underweight patients require 3,000 to 3,600 calories daily, depending on their activity and body size, in order to gain weight at an appreciable rate.

Just as in the case of the obese patient, careful dietary instruction is important in the treatment of the underweight person. A 3,000 calory diet suitable for an ambulatory underweight person is given in tables 1 and 2.

For the patient with frank anorexia nervosa the services of a dietitian are most helpful. An estimate of the habitual caloric intake of these patients should be made by the dietitian. This usually will be found to be within 900 and 1,300 calories. The patient is then fed a diet containing 300 calories more per day than the estimated habitual intake, and at intervals of three to ten days as tolerated the diet should be increased by steps of 300 calories. The usual sequence is 1,300, 1,600, 1,900, 2,200, 2,500 and 3,200 calories.[10] Before treatment is started the patient should be told frankly that there will be a certain amount of abdominal discomfort with the increased diet but that this will become less and disappear with time. The patient should remain under supervision of the dietitian until the caloric intake has been stepped up at least twice, so that some measure of success is assured. Then the dietary instruction entails only two or three more steps to attain the necessary 3,000 or more calories for continued gain in weight. Constant encouragement and reassurance are necessary throughout the course of treatment. As in the treatment of obesity, the success of dietary therapy of anorexia nervosa is proportional to the strength of the physician's conviction that diet will succeed and to the ability of the physician to transmit that conviction to the patient.

Gain in weight on high caloric regimens and loss on reduction diets frequently proceed in a stepwise fashion, so that periods of as long as seven to ten days without appreciable change in weight followed by rapid gains or losses may occur.[20] This phenomenon is most likely a reflection of variations in amount of extracellular fluid and is no cause for discouragement, since a normal water balance will ultimately be attained. Restriction of salt may diminish the magnitude of this phenomenon but will have little or no effect on the final loss or gain in weight. These periods in which the weight fails to change, inaccurately measured diets and failure to allow for the energy expended in physical work or in useless movements are three of the reasons why some physicians have expressed the opinion that there are certain obese persons whose weight cannot be reduced by diet alone and that some lean patients will fail to gain weight on a high caloric diet.

With rigid adherence to a properly planned diet and with patience, one can confidently expect response in practically every case of leanness or obesity. The emaciation secondary to hyperthyroidism or to impaired gastrointestinal function, such as with sprue or chronic relapsing pancreatitis, constitutes an exception to this rule.

*Psychotherapy.*—It has recently been the fashion to ascribe obesity and leanness to psychologic and psychiatric factors and to emphasize psychotherapy in treatment. While not wishing to minimize the importance of these factors, we should like to remind the reader that many of these patients fail to demonstrate significant psychologic deviation and require no formal psychiatric therapy. These persons should be warned frankly of the dangers of their obesity or leanness and told that the only effective treatment is proper diet. The obese patient should be reassured that the reduction program will not harm him and that a familial tendency to, or the long duration of, obesity is no bar to therapy. He should be warned to disregard relatives and well-meaning friends who unconsciously, unintelligently or jealously associate loss of weight with ill health and tell him daily that "this diet makes you look terrible." The patient should be carefully instructed in his dietary program; simply handing him a sheet of instructions and telling him to follow them usually fails because the patient's understanding of the directions is incomplete and because the offhand manner of the physician lessens the patient's respect for the diet. The success achieved is usually proportional to the confidence of the physician in the dietary program. Regular office visits are important to maintain the morale and the determination of the patient to adhere to the diet. Limitation of space prevents discussion here of the problems posed by the patient with significant psychologic aberrations. Discussion of such problems may be found elsewhere.[21]

*Other Therapy.*—In obesity certain adjuvants to dietary therapy have been suggested.

It has been demonstrated that amphetamine sulfate ("benzedrine sulfate") and its dextrorotatory isomer, "dexedrine," will diminish appetite.[22] It is to be emphasized that amphetamine affects obesity only through the mediation of appetite, and the compulsive eater may continue to eat excessively and therefore may derive no benefit.

A certain degree of tachycardia, hypertension and elevation of the metabolic rate for several hours are known to follow administration of single large doses of amphetamine.[23] Although these undesirable effects may occur after large isolated doses, the hazard is probably less than appears at first glance. First, such cardiovascular effects of these sympathomimetic drugs tend to become lessened with continued administration.[24] Second, relatively small doses which would cause minimal circulatory effects should be adequate to "take the edge" from the appetite. In view of the adverse effects on the cardiovascular system, it would seem doubtful wisdom to increase the dose if customary amounts fail to alter eating habits, since the circulatory system of the obese person is already laboring under an increased strain.[25] The dose of racemic amphetamine sulfate used by Harris, Ivy and Searle[22] was 10 to 15 mg. three times a day, while the dose of the dextrorotatory form was half that. These amounts probably should be regarded as maximal, particularly since Albrecht[26] found doses of 5 mg. of racemic amphetamine sulfate to be effective.

Most physicians do not believe it wise to prescribe such medicines without dietary instruction because the patient, anxious to lose weight, may select a diet inade-

quate in such essentials as protein or calcium, or he may rely on the drug and continue to eat freely.

We rarely find it necessary to use such drugs because appetite usually diminishes in the first week of dietary restriction, and we avoid their use because the prescribing of any drug removes the emphasis from diet. We do not wish to give the impression of opposition to these drugs but desire to reemphasize the paramount importance of diet in the therapy of obesity.

Early in the study of obesity it was erroneously assumed that hypothyroidism was a frequent cause of overweight. From this hypothesis it was a logical step to prescribe desiccated thyroid as replacement therapy. But since hypothyroidism has not been shown to be causally related to obesity, this justification for the use of thyroid has been removed.

Some practitioners have even used large doses of thyroid to create a state of hyperthyroidism, but in consideration of the dangerously toxic effects of this substance on the heart,[27] such a practice is not advised.

In short, we do not advise the use of thyroid in the treatment of obesity. Small doses seem to be inactivated,[28] while larger doses exert a direct toxic action on a heart[27] that is already burdened by the stresses imposed by obesity.[25]

Exercise has been demonstrated to be an inefficient means of disposing of an excessive intake of energy.[2] Newburger has estimated that a patient must walk 36 miles (58 kilometers) to rid himself of 1 pound (0.5 Kg.) of adipose tissue. Exercises, massage and local applications of heat have no effect on local deposits of fat.[29] Diuretics and heat therapy designed to increase perspiration may give both the physician and the patient a false sense of achievement by causing the excretion of a few pounds of water. Laxatives and colonic irrigations have not been shown to be effective in diminishing the absorption of food and are of no apparent benefit. A variety of other medications, such as atropine, digitalis, various endocrine preparations, both salts and glucose, has been used in obesity with no proved benefit. Dinitrophenol is no longer used because of its toxicity.

The only important adjuvant to diet in the correction of leanness is rest. Rest diminishes output of energy, allowing the increased intake of food to be retained in the form of body tissue. Rest also often may be employed to aid the tense anorexic patient to eat more freely. Vitamin deficiencies are unusual in association with the ordinary leanness seen in this country, and there is no convincing evidence of a strong appetite-stimulating action of any of the vitamins. For this reason it is not necessary to prescribe supplementary vitamins for the underweight person unless there is a history or clinical evidence of a deficiency. A well planned diet contains all necessary vitamins (table 2). Adding a multivitamin preparation can do no harm, however.

Insulin is a strong stimulant to the appetite when given in amounts sufficient to cause hypoglycemic symptoms, but benefits from such a practice scarcely justify the means. Doses of insulin insufficient to cause hypoglycemic symptoms have not been shown to stimulate the appetite[30] except by the device of suggestion or the threat "now you've got to eat or go into insulin shock."[31] For these reasons we rarely employ insulin as a stimulant to the appetite.

### SUMMARY

Overweight is a serious menace because it appears to increase the incidence of many degenerative diseases. A reduction program is the most important weapon for combating such diseases. Underweight is reported to increase the susceptibility to tuberculosis but moderate underweight is a desirable state in the person past 40 years of age.

The cause of obesity and leanness is a disproportion between caloric intake and caloric requirement. The therapy of obesity or leanness consists of the correction of this disproportion by means of diet.

Administration of amphetamine in appropriate cases may occasionally be a useful adjuvant to dietotherapy, while psychotherapy is often of greatest importance in the case of underweight or overweight persons.

Diuretics, atropine, digitalis, desiccated thyroid and various endocrine preparations all accomplish little in reduction programs. Massage and exercises are ineffective in removing localized deposits of fat. Exercise is an inefficient means of disposing of excessive intake of energy. Insulin is impractical and vitamins ordinarily are ineffective in stimulating the appetite of lean persons.

The diagnostic terms "Simmonds' disease" and "Fröhlich's syndrome" (adiposogenital dystrophy) have been widely used, but their use is rarely justified. Dercum's disease (adiposis dolorosa) has not been demonstrated to be an entity.

## DELAYED BRACHIAL PLEXUS PALSY DUE TO UNUNITED FRACTURE OF THE CLAVICLE

### Report of a Case

ELDRIDGE CAMPBELL, M.D.
WILLIAM P. HOWARD, M.D.
and
CHARLES W. BURKLUND, M.D.
Albany, N. Y.

The discovery of the syndrome of the ruptured cervical disk has greatly accentuated interest in arm and shoulder pain. Arthritis, neuritis, cervical rib, aneurysm, trauma and the involvement of the brachial plexus by benign or malignant tumors have long been familiar. Much has been written about scalenus anticus syndrome. The following case is unusual because of the symptoms which developed several years subsequent to the injury and nonunion of a fractured clavicle.

### REPORT OF A CASE

J. G., a 46 year old white veteran of World War II, was admitted to the Albany Hospital with the chief complaint of weakness and numbness of the right hand. Ten years previously he had sustained a fracture of the right clavicle. After several days of procrastination he consulted a physician, who bandaged his arm tightly to his side with the elbow flexed. A lump per-

sisted at the site of fracture but was not painful and did not in any way interfere with his work as a laborer. Three years before admission, while serving overseas in the Army, he noted that his entire right arm became numb or felt "asleep" whenever he carried a pack on long hikes. As soon as the pack was removed the arm would again feel normal. He observed no weakness or color changes of the limb at that time. A year later, he first became aware of numbness of the fifth digit of the right hand. During the following year this numbness spread to involve the third and fourth digits as well as the corresponding volar and dorsal surfaces of the hand. There was no change in the intensity of the sensory disturbance. Six months prior to admission he experienced weakness of the right hand, which steadily increased. He found difficulty in opposing the thumb to the fifth finger, in holding a pencil and in the performance of finer movements; it became necessary for him to change from a straight edge to a safety razor for shaving. He stated that he had no pain in the hand, forearm, arm, shoulder or neck. Atrophy of the interosseus muscles was observed two months before admission. Past and family histories were noncontributory.

Examination revealed a robust compactly built man of small stature. The blood pressure was 120 systolic and 90 diastolic in both arms. With the arms hanging at the sides, the radial pulse on the right became decidedly reduced in volume and at times imperceptible. With the arms held horizontally, the two radial pulses were equal. The veins, more notably the cephalic, were comparatively distended in the right arm. No fever or color changes were observed. A bony nontender mass was present on the middle third of the right clavicle, almost doubling its size over a distance of 4 or 5 cm. Pressure on this mass produced an abnormal amount of movement and some crepitus. Motions of the neck and shoulder joint were normal. Slight atrophy of the interossei was present in the right hand, especially of the first dorsal. The right grip was definitely weaker than the left, particularly of the third, fourth and fifth fingers. (The patient was right handed.) Hypoesthesia and hypalgesia were present over the usual ulnar distribution on the right. Fasciculations were not observed. The myotatic reflexes were equal and active bilaterally. The results of the remainder of the general physical and neurologic examinations were negative.

*Laboratory Data.*—Results of routine laboratory studies were all within normal limits. Roentgenographic examination revealed an overriding ununited fracture at the junction of the outer and middle thirds of the right clavicle (fig. 1). On fluoroscopy motion was readily observed on abduction or adduction of the arm. The cervical part of the spine was normal, and no cervical rib was demonstrated.

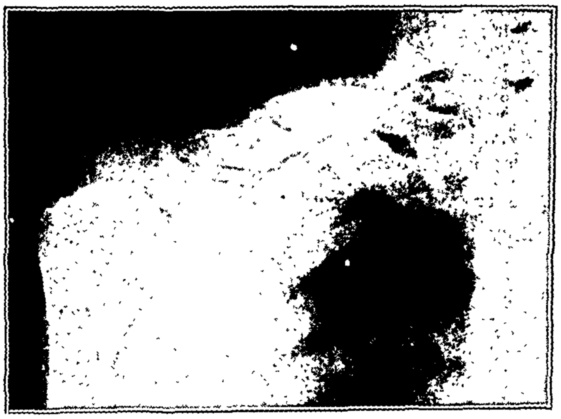

Fig. 1.—Roentgenogram showing the ununited fracture of the clavicle with excessive callus.

*Operation.*—On Dec. 2, 1947, the right clavicle was exposed under general anesthesia. A large glistening callus and a great deal of scar tissue surrounded the old fracture site. Most of the callus surrounded the distal fragment, which was displaced under the proximal fragment. This large mass (fig. 2) pressed directly on the subclavian artery and the lower trunk of the brachial plexus. Both fragments and the callus were resected with the Gigli's saw, thus leaving only the proximal and distal quarters of the clavicle. The wound was closed with interrupted sutures of fine silk without drainage. The postoperative course was uneventful. The sutures were removed on the fourth postoperative day, and the patient was discharged on the fifth day after operation.

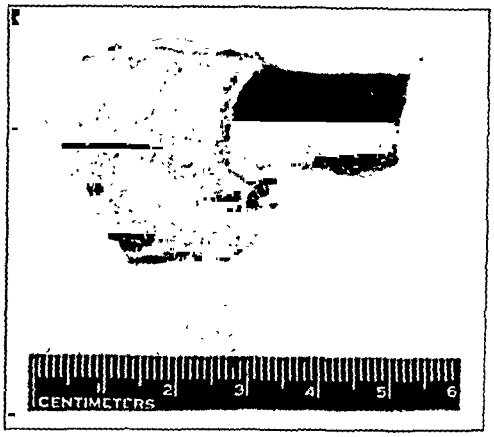

Fig. 2.—Portion of lateral fragment which overlay the brachial plexus.

*Postoperative Course.*—Both the sensory and motor symptoms disappeared rapidly and at the time of reporting (seven months later) were hardly discernible. Within four weeks he returned to heavy labor and apparently suffered little or no inconvenience attributable to the resection of the midportion of his clavicle. The radial pulse was palpable with the arm at the side, and the arm veins were no longer distended.

## COMMENT

While ununited fractures of the clavicle are generally considered unusual, we have been unable to find a satisfactory statistical study of their incidence. They are commonest at the juncture of the middle and outer thirds. Symptoms of brachial plexus involvement occurred in 6 of 9 cases reported by Berkheiser,[1] but in only 3 of 20 cases reported by Ghormley and his colleagues.[2] Shelden [3] made similar observations. Little stress was made in these reports of the time interval between the injury and onset of brachial plexus symptoms.

The costoclavicular space which, under normal conditions, is more than adequate to accommodate the brachial plexus and subclavian vessels, is seriously impinged on in ununited fractures by the inward and downward displacement of the proximal end of the distal fragment. When this space is further encroached on by the formation of callus, the structures passing through it are compressed. These factors plus the motion in the false joint produced are responsible for the symptoms which occur. In the case reported herein the long oblique distal fragment and its callus extended downward and medially and underrode the medial fragment when the arm was adducted; this probably accounted for the obliteration of the radial pulse in arm at side posture and its reappearance when the arm was abducted.

Subperiosteal resection of the middle third of the clavicle did not result in significantly impaired function, but produced immediate and permanent relief of symptoms.

## SUMMARY

An instance of delayed palsy of the brachial plexus and compression of the subclavian vessels by an ununited fracture of the middle part of the clavicle is reported. Rapid relief of symptoms followed resection of the two medial quarters of the bone.

# Council on Pharmacy and Chemistry

## REPORT OF THE COUNCIL

*The Council has authorized publication of the following report.*
Austin Smith, M.D., *Secretary.*

## CANCER AND THE NEED FOR FACTS

In this age of enlightened scientific advancement it seems incredible that the known facts concerning cancer continue to be distorted in the minds of the public and the medical profession through the sale of useless or doubtful remedies for the treatment of this disease. Some such remedies are outright frauds, while others are in need of further investigation but, nevertheless, are offered for clinical application. Unfortunately, some of the more promising remedies occasionally are publicized prematurely and much confusion and some harm occur.

At the present time the established treatment for cancer consists of the judicious use of surgery and irradiation, either with gamma rays or roentgen rays. Many promising discoveries, such as the effect of substances with estrogenic activity on certain types of cancer, have been made which offer hope that some day drug therapy may become an important treatment measure, but until further research work has been completed, the use of drugs must, for all practical purposes, be regarded as still in the experimental stages. Furthermore, the injection of radioactive elements offers promise of an improved method for irradiation of certain forms of cancer, but it, too, requires extensive study before a therapeutic evaluation can be made finally. Thus a drug cure for cancer has not been found, and, until scientific research can provide a successful agent or method capable of preventing death from the disease, emphasis must continue to be placed on the early detection and complete eradication of the disease at its outset.

### I. FRAUDS AND FABLES

Of all the nostrums fraudulently promoted as remedies or "cures" none is more reprehensible than those falsely claimed to be effective for the treatment of cancer. The variety of preparations offered as remedies for cancer bears eloquent testimony of the failure of such products to provide a "cure," or even a sound method of treatment for the disease; nevertheless, the sale of quack remedies for cancer continues. Such nonsense is due in part, to the unscrupulous promoters who are persistent in their false appeals to the uninformed, and in part to those sufferers who are easily persuaded to forego scientific examination and treatment for more magical shortcuts. A less obvious but equally guilty minority, however, is constituted by a few presumably qualified physicians who lend unintentional support to worthless remedies by prescribing or administering such products with the wishful notion that they may provide some benefit in the treatment of what is known to be incurable cancer. The cancer charlatans thus prey not only on persons without cancer who fear it and on patients with the disease who have not sought competent medical advice, but also on the physician who is ever hopeful that a real cure for the disease has been found.

#### "COLLODAURUM"

Perhaps one of the most insidious of all the cancer nostrums is the so-called "palliative" promoted with insinuations that it is of some benefit and may possibly cure. "Collodaurum," a 0.02 per cent preparation of colloidal gold ("2/1000 grain in each ten minums"), promoted by the Kahlenberg Laboratories, Sarasota, Fla., belongs in this class of cancer nostrums. Advertising sent to physicians cleverly emphasizes the use of this product as a palliative in the treatment of inoperable and postoperative carcinoma in the manner for which roentgen or radium treatment is scientifically used to destroy or discourage the spread of certain malignant tumors. The unwary physician is further tempted by the statement, "A small number of so-called hopeless cases are cured and remain cured." This is, of course, pure balderdash. Ten years ago the Council exposed the character of the claims made for this product and concluded that it was useless in the treatment of cancer.[1] Although it was then pointed out that there is no scientific proof that gold is appreciably absorbed when given orally, the firm continues to advertise, "administration may be oral, intravenous or both." Then, as now, there existed no sound evidence to demonstrate that colloidal gold or, indeed, gold in any form by any route of administration is of any real benefit for the palliation or cure of cancer, and, since the Council's previous report, nothing has been brought forward to indicate that "collodaurum" is anything more than a placebo to which curative properties are falsely assigned on the basis of uncontrolled clinical impressions. As has been often emphasized, the fluctuation in the clinical condition of many patients with cancer accounts in large part for the benefits attributed to preparations such as "collodaurum."

That this product is not the specific remedy the promoter claims is evident from its history. The record shows that the product was also previously promoted for colloidal gold therapy of arthritis and tuberculosis, though Kahlenberg Laboratories now separately promotes a more concentrated (0.1 per cent) colloidal gold preparation for arthritis under the name "rexarum," with the claim that it is effective orally as well as by injection. This manipulation removes "collodaurum" only slightly from the category of the "cure-all" nostrums promoted for a wide variety of diseases. The firm's claim that "collodaurum" is unlike other gold preparations parallels its statement that the product is "absolutely free of soluble gold salts." This is evidently intended to create the erroneous impression that gold in colloidal form possesses mystic healing qualities and is superior to the soluble salts, such as gold and sodium thiosulfate, N.F. Indeed, the existing evidence for any beneficial effects of chrysotherapy is based on the use of soluble gold salts, the action of which is attributed to the absorption of the injected gold, whereas authorities on chrysotherapy have found that colloidal gold preparations are generally ineffective therapeutically because insoluble colloidal particles are quickly phagocytized and would thus be prevented from being readily absorbed. The Council has not accepted preparations of colloidal gold for any purpose.

---

[1] Collodaurum Not Acceptable for New and Non-Official Remedies, report of the Council on Pharmacy and Chemistry, J. A. M. A. **111**: 531 (Aug. 6) 1938.

### "IRIODINE" AND "RADIODINE"

Promoters of other nostrums have also found it expedient to attribute magical properties falsely to the colloidal state of various substances. Prominent among these are the colloidal iodine preparations promoted through a concern lately known as the Iodine Research Institute of Chicago, by a Belgian chemist, Albert Trencavel. One of the products attributed to these promoters is advertised to physicians under the name "iriodine," and to the public as "blue magic iodine," and is claimed to be effective in a variety of conditions, including cancer, by a combination of oral and topical administration. This product is vaguely described as "free iodine in aqueous solution-dispersion suspended by a special process in a live or active colloidal medium to which it is 'harnessed,' insuring its stability." The promoters are also responsible for a product named "radiodine," at one time described as "colloidal iodine sine potassium iodide, for intravenous injection only," and at another time as, "a mild radio-active form of iodine in its pure form. . . ." Apparently the promoters have found it difficult to decide whether or not injected iodine should be in colloidal or radioactive form. Preparations containing iodine in colloidal form are not new, and over the years various pharmaceutical manufacturers have "introduced" such products with fanciful therapeutic claims for their superiority over iodine in noncolloidal form. Likewise other preparations claimed to be "radioactive" have long been credited with unusual healing powers, when as a matter of fact the amount of radioactivity was either imaginary or of the order of that from a radium-coated watch dial. Such obviously worthless remedies should not be confused with the truly radioactive elements, such as $I^{131}$, which is under current scientific investigation for the treatment of carcinoma of the thyroid and toxic goiter.

### CAUSTIC PASTES

A report on cancer frauds would not be complete without reference to the topically applied escharotic preparations promoted for the caustic removal of superficial tumors by what has been described as the method of "chemosurgery." The type of product usually employed is merely a caustic paste containing arsenic, zinc or other escharotics, or some combination of such substances, used either for complete removal or delineation of external cancer as a preparation for surgical removal. The promoters of "collodaurum" mentioned herein also market a preparation of bichloracetic acid which belongs in this class. THE JOURNAL has previously pointed to evidence showing that the promiscuous use of such preparations accomplishes nothing that cannot be equally well, or better, done by irradiation or surgical treatment.[2] THE JOURNAL'S brief review of the results of this type of treatment received by patients at Dr. Nichols' Sanatorium, Savannah, Mo., has served to emphasize the dangers involving the use of caustic pastes; the treatment produces unnecessary disfigurement in patients without true cancer, and the locally applied paste does not prevent the advance of extensive or deep-seated superficial tumors without surgical treatment or radiation therapy.

Apparently another outlet for this form of cancer "cure" is the Hoxsey Cancer Clinic, Dallas, Texas, which has been claimed to use an arsenical paste for treatment. The record of its promoter, Harry M. Hoxsey, has been reviewed by THE JOURNAL.[3] Recent information[4] indicates that the activities of this promoter extend into Mexico and that the treatment also includes the internal administration of a mixture of potassium iodide, cascara sagrada and some other "secret" ingredient.

The most serious aspect of the treatment for cancer with escharotic pastes and, indeed, all cancer nostrums, is that some patients with real cancer are deprived of scientific examination at a time when the spread of the disease and death might be prevented. Cancer that is evident on the body surface in its early stages usually arises from the skin, whereas most internal cancer rarely involves superficial structures such as the skin except as the result of widespread extenson of the disease from internal organs or glands. It is thus utterly foolish to expect a "cure" by the application of caustic pastes to the superficial manifestations of a tumor that may involve remote internal tissues. The nostrum vendors are, of course, more concerned with the fee for their dubious services or products than with accurate and complete diagnosis, since they lack either the scientific training or the inclination to help the unfortunate victims of their advertising. Many of the promoters have no qualifications or license to practice medicine, a situation that some of them have tried to meet by alining themselves with unethical licensed practitioners who are equally unfit or disinclined properly to diagnose and treat cancer.

The need of microscopic control for the proper use of caustic paste to fix tumor tissue preparatory to successful surgical removal of superficial cancer has been recently reported.[5] This approach differs, however, as it involves a scientific approach to the concurrent use of a caustic paste; it is not intended as a curative agent.

### "SYNTHETIC ANTITOXINS"

Another well known abuse in the annals of cancer quackery is the use of the so-called Koch cancer treatment, which is neither an effective treatment nor one restricted always to cancer. Since 1920, a William F. Koch, M.D., of Detroit has promoted a series of preparations under one or more names or in various forms, distributed by Koch Laboratories of the same city; he calls these preparations "Koch's synthetic antitoxins." The products have been foisted on the medical profession and the public in what the promoter apparently claims to be three different forms, represented by the following [illegible] "[illegible]lide," "1:4 benzoquinone" or [illegible]" or malonide ketone solution." The promoter has never satisfactorily explained the nature of these preparations, if, indeed, he himself has any knowledge of their composition, so that it is impossible to determine with certainty whether the variously identified products are actually different or are merely different names or different forms of the same nostrum. THE JOURNAL and the Bureau of Investigation of the American Medical Association have repeatedly condemned the promotion of these products.[6] The records of the Association indicate that within less than a year of his graduation from a Detroit medical college in 1918, the promoter announced that he "had developed a real specific cure for cancer," then described only as "Koch's synthetic anti-toxin" and claimed to be a differential poison that would destroy the "cancer germ" without injuring the host. Koch advanced the theory that cancer was caused by a microorganism resembling the spirochete of syphilis and exploited his nostrum as a cancer "cure" for several years before extending claims to other diseases. "Glyoxylide," appearing on the scene in 1936, was claimed to have "demonstrated its efficiency not only in the treatment of cancer, but also in such infections as tuberculosis, psoriasis, leprosy, poliomyelitis and syphilis," despite the fact that an investigation of the results of his "cure" for cancer indicated that it was of no value and that patients with the disease receiving the treatment had subsequently died. Koch vaguely represents "glyoxylide" to be a compound resembling an unsaturated diketone and claims that this and his other so-called synthetic antitoxins act as catalysts to encourage the destruction of toxins that are held to be responsible for the growth of cancer tissue. There is, of course, no scientific basis for this theory of cancer, but it illustrates the obvious fact that Dr. Koch has either changed his mind regarding his theory of the cause of cancer or purposely alters his pseudoscientific jargon from time to time to confound the unscientific practitioner and layman alike.

[7] Omitted.

Koch continues to play on the credulity of the unwary physician and the human victims of cancer and other diseases with testimonials of false cures or benefits both in this country and in Canada, where representatives for his nostrums also operate. Since 1940 his quackery has also extended to the field of veterinary medicine, with claims for his nostrum in the treatment of mastitis and other diseases in cattle. It has been implied that the value of "glyoxylide" for such purpose has been confirmed by successful experiments conducted under the auspices of the provincial department of agriculture of British Columbia. An exposé of this additional falderal recently appeared in The Journal.[8] It should be obvious that Koch's treatment is worthless as a remedy for any disease. Koch's "treatment" is known to be prescribed chiefly by irregular practitioners who are not doctors of medicine and who extend his fraudulent operations by their dubious support.

### HETT "CANCER SERUM"

In a pamphlet bearing the title "The Hett Cancer Treatment and Research Foundation" and listing an address in Windsor, Ontario, Canada, a Dr. John Emil Hett, who has had other Canadian addresses, publicizes to physicians of this country the use of a serum alleged to cure cancer. The exponents of this "cure" also claim to detect accurately the presence and degree of internal cancer from a drop of the patient's blood that is merely allowed to dry on a glass slide which is furnished for forwarding the specimen by mail. It is modestly stated further, "The cure of cancer has been discovered (namely by Dr. Hett) as far back as 1931," and "Dr. Hett has not been able to bring his discoveries to the notice of the profession through the columns of a medical journal because editors decline to publish a paper on the subject unless details are given about the nature and method of preparation of his serum." The explanation is said to be made clear in his book, "Cancer, Its Causes, Prevention and New Treatment," which, apparently, will be sent anywhere for $3.50. Several flimsy excuses are offered in defense of the secrecy of the formula for the serum, not the least of which is the claim that a physician needs special training to administer the serum safely. As an example of the danger of administration by inexperienced hands, it is stated in the pamphlet, ". . . there were cases of fatalities from the use of ensol, where the agent had been prepared elsewhere than in the inventor's laboratories." The former history of "ensol," an extract of cancer tissue for injection, and its tetanus-contaminated companion, "rx," has been previously reported in The Journal.[9] The pamphlet offers as another excuse for secrecy by Dr. Hett the point that members of the Royal Commission appointed in 1937 by the Legislature of Ontario to investigate all remedies used in the treatment of cancer apart from surgery, roentgen rays and radium were sworn to secrecy as to the nature of the formulas submitted to that agency for examination. It is further indicated in the pamphlet that the Commission was at first "ultraconservative" toward Dr. Hett's treatment, but that it ultimately admitted the cures attributed to him. The complaint is offered that the findings of the Commission reported to the Legislature in 1945 were not made public until 1946, after considerable pressure on the part of Dr. Hett and his associate.

The secrecy surrounding the serum "cure" of Dr. Hett can only be condemned as outright chicanery. If, indeed, a cure for cancer had existed since 1931 as claimed by Dr. Hett, then the responsibility for all deaths from the disease since that time could be ascribed to his failure to make known his discovery to all other physicians. Obviously, the real reason for secrecy lies in the fact that Dr. Hett has no cure.

### "AF-2"

More recently, publicity concerning another alleged "serum" cure for cancer, known as formula "AF-2," has come from Italy by way of an American-Italian language newspaper containing an item regarding the Italian inventor of the preparation, a Prof. Francesco Guarnieri. The manufacture and distribution of the preparation are attributed to an Institute Guarnieri of Rome, Italy. One American newspaper makes reference to the product as a "serum" derived from the livers of "cancer-resisting" animals, such as goats, sheep and pigs, and indicates that although Guarnieri claims to have cured or arrested many cases (of cancer) by free distribution of the preparation, he is not in good repute with Italian doctors and specialists. Despite failure of the government medical commission of Italy to approve the sale of the formula in that country, the inventor has apparently condoned the martyrdom accorded him in the Italian press, publicizing the popular clamor that the product be given official recognition. Another source of information indicates that Professor Guarnieri is not a physician and that he has been unwilling to document his cases of claimed cures or to give details of the composition of his material. It is understood that tests of "AF-2" are being conducted in Italy and that the results so far are unfavorable. An American veterinary authority has offered the pointed comment that livestock ordinarily sold for slaughter, such as swine, rarely live long enough for any one to state with certainty that such animals are free of cancer. This would appear to shed considerable doubt on the theoretic basis for the animal origin of "AF-2." Furthermore, even if certain animals are "cancer-resisting," there is no scientific proof that an extract of their livers contains any substance capable of curing what is known as cancer in human beings.

### DIETARY "TREATMENTS"

Although reference to the influence of the diet is frequently included by promoters of cancer nostrums as a part of some unproved theory of the disease, perhaps the most notorious adherents to the false notion that the diet has any specific influence on the origin or progress of cancer are the food faddists. One such faddist, Johanna Brandt, author of a book entitled "The Grape Cure," represented that the eating of grapes alone would cure cancer and practically all other human diseases. The book was last distributed by a Jessie F. Springer, operating as the Harmony Centre, Inc., of New York. The organization capitalized on the "grape cure" propaganda by advertising that it had grape juices and concentrates for sale. The distributor has been cited in a cease and desist order issued by the Federal Trade Commission that the misrepresentations contained in the book be discontinued.[10] The United States Post Office Department subsequently issued a Fraud Order (No. 36728, Feb. 27, 1948) against the distributor for use of the mails to advertise and circularize various "health books" advancing fraudulent claims for dietary cures of such conditions as high blood pressure, faulty eye sight and gray hair.

Another "treatment" for cancer involving dietary restrictions is that of a Dr. Max B. Gerson of New York City, who has been reported by THE JOURNAL[11] to be using a dietary and salt-controlled method that is said to be supported by a Robinson Foundation for cancer research located at 14 Wall Street, New York. THE JOURNAL pointed out that Gerson had been previously connected with a diet method falsely proposed as an advance in the treatment of tuberculosis and that the research "foundation" for cancer was actually financed by two business enterprises, the Hatfield Wire and Cable Company and Wellin Davit and Boat Company, both of Amboy, N. J., by incorporation under a provision of the revenue code for educational institutions to exempt the organization from federal taxes. The detailed "diet" proposed by Gerson consisted essentially in restriction of all foods other than uncanned fresh fruits and vegetables and oatmeal and forbade the use of aluminum utensils and pressure cookers in preparation of food and the use of such items as salt, spices, sodium bicarbonate, alcohol and tobacco. His "treatment" also included the internal administration of iodine, liver, iron and various vitamins (apparently to supplement a diet lacking in essential proteins and fat) and the use of an enema formula to produce copious daily bowel movements. The diet was said to make the body highly hypersensitive, so that ordinary anesthesia might be fatal, a conjecture that is wholly unfounded and apparently designed to appeal to the cancer victim already fearful of a surgical operation which might offer the only effective means for eradication of the disease. However, there is no scientific evidence whatsoever to indicate that modifications in the dietary intake of food or other nutritional essentials are of any specific value in the control of cancer.

An equally vague form of alleged cancer therapy that may be included in this category is that attributed to Emanuel Revici, said to be a refugee physician from Rumania. The history of the "treatment" promoted by this person begins in Mexico City, where patients from the United States were attracted by claims of a new method. An investigation by several American physicians previously reported in THE JOURNAL[12] indicated that the modern building used for hospitalization of patients was without adequate laboratory or other scientific facilities, that no satisfactory clinical record of patients was kept and that the so-called treatment, based on unproved theories, consisted of the parenteral and oral administration of various glandular and tissue brews digested in various ways. The investigators warned that little benefit could be expected by cancer patients going to Mexico City for this "treatment." Subsequently, Revici spent a few months at the University of Chicago, where he was given an opportunity to demonstrate his method, with the result that in 52 patients with cancer no favorable effects could be attributed to this form of therapy. Present records indicate that Revici has been in Brooklyn since 1946 at what is called the "Institute of Applied Biology"; his "treatment" consists essentially of the administration of fatty acids by mouth and by injection under the skin, to induce a gain in weight. While it is possible to credit fatty acids with the ability to produce a gain in weight in patients with cancer, as enforced food intake would do, there is no scientific evidence to indicate that this will alter the ultimate course of the disease.

### "ORGONE ACCUMULATOR"

Among the various weird devices at one time or another offered for the "treatment" of cancer and other diseases should be mentioned what has been described as the "orgone accumulator" and "orgonoscope" in a book entitled "The Discovery of the Orgone. Volume II: The Cancer Biopathy," by Wilhelm Reich, M.D., translated by Theodore P. Wolfe, M.D., published by the Orgone Institute Press of New York. The "orgone accumulator" is apparently a cabinet in which the patient sits and supposedly accumulates "orgone," a highly imaginary sexual factor supposedly found everywhere in life, but somehow not effective unless concentrated about the patient. The pseudo-freudian confusion on which this illusory concept of "treatment" for cancer is based can be best appreciated by the following comment concerning the book:

> The neatness of its format and the unctuous effect of its pseudo-scientific vocabulary are likely to mislead some of the readers of this book. It begins with a baffling description of units called "bions"; the noun gives rise to derivatives like the phrase "bion water" and the adjective "bionous." The earth bion water contains something called "orgone," which has to do with orgasms. "OP" in this vocabulary means not "osmotic pressure" but "organotic potency"; related terms are "orgone accumulator" (illustrated on page 100), "orgonoscope" (illustrated on page 89), "orgonomy," "orgonotically," "anorgonia," and even "orgprotozoa." The blueness of the sky is ascribed to orgone. Sooner or later the author sees blueness practically everywhere, even in red corpuscles.

---

[10] Abstracts of Certain Federal Trade Commission Releases: Grape Cure For Cancer, report of Bureau of Investigation, J. A. M. A. **116**: 2525 (May 31) 1941.

[11] Gerson's Cancer Treatment, editorial, J. A. M. A. **132**: 645-646 (Nov. 16) 1946.

[12] Correspondence: A Mexican Treatment for Cancer—A Warning, J. A. M. A. **128**: 1186 (Aug. 18) 1945.

The thesis of the book is that cancer is somehow related to the behavior of orgone, and (page 350) that "a local cancer affection is a result of a disturbed sex-economy of the organism. Consequently, a radical fight against cancer requires a radical change in the sexual hygiene of the total population." To reach this conclusion, the author, without exciting any protest from the translator, weaves a web of argument in which the undeniable is most amazingly entangled with the unfounded and the absurd. As a defense of the author's use of the "orgone accumulator," this book fails of its purpose.

Inquiries received concerning the "institute" publishing this nonsense indicate that the "theory" is promoted as a method for curing cancer. There is, of course, no evidence to indicate that this is anything more than another fraud that has been foisted on the public and the medical profession.

### OTHER CLAIMED CURES

The files of the Bureau of Investigation and of the Therapeutic Trials Committee of the American Medical Association contain many letters from persons purporting to have a formula for a salve or other type of medication believed to be of benefit as a "remedy" for cancer. Many such persons are sincere but misguided in their efforts to bring such medicaments to the attention of the medical profession, basing their faith in a particular formula handed down within the family or on the testimony of life-long friends who were thought to be benefited, when actually cancer had not been proved to be the cause of their ailment. The lack of scientific knowledge makes it difficult for these persons to disbelieve the apparent "cures" brought to their attention by other equally uninformed persons. Others are similarly deluded by unscientific evidence of "cures," but for selfish reasons do not want to reveal the nature of their claimed remedy, even though they profess to be motivated by altruistic desires. These persons, of course, differ from the charlatan only by their lack of knowledge or ability to set up a scheme of promotion on a commercial scale and are thus more to be pitied than condemned. Most of what may be called these "home remedies" for cancer are extracts of plants, herbs or other galenicals to which little if any therapeutic action can be assigned.

In answer to the many letters from persons sincere in the belief that they have a curative remedy for cancer who propose that it be investigated by the American Medical Association, the Bureau of Investigation has replied that before such remedies could be properly evaluated the following information must be furnished: (1) full information regarding the composition; if it is composed of more than one substance, the full name and amount of each substance; (2) the names and addresses of at least twenty-five persons who are alleged to have been cured by the use of the treatment, and (3) the names and addresses of physicians who had the opportunity of diagnosing the condition in these twenty-five persons before they were treated.

In every instance the request for such information has not been met.

## II. UNESTABLISHED REMEDIES

Finally, it should be added that there are under investigation various methods of treatment proposed for cancer that cannot be classified as frauds, but which are based on unestablished theories of questionable promise. Such remedies sometimes receive so much early and enthusiastic publicity in the press that the relatives of cancer victims and the victims themselves are falsely encouraged to believe that a complete cure for the disease is at last available. Sometimes such publicity occurs through no fault of the investigators and is not necessarily an indication that commercial promotion is contemplated or that the effort to find a treatment of real value is not sincere. Often, also, the considerable time required for scientific evaluation of what is reported to be a promising agent makes it impossible to estimate the status of the proposed treatment until other scientists have repeated experiments and confirmed the report. Because so many promised "cures" have failed to be of any real value for the treatment of cancer and of other serious diseases, it is only natural for the honest investigator to have a healthy skepticism toward new claims for such a treatment.

### "KR SERUM"

"KR serum" (so designated with the initials of the surnames of the two original Russian investigators, N. G. Klyueva and G. I. Roskin), which is made from the serum of mice or from cultures infected with certain strains of a protozoan, Trypanosoma cruzi, the cause of a serious tropical illness called Chagas' disease, has been claimed by Russian investigators to contain an "endotoxin" which when injected subcutaneously into mice with certain forms of cancer will cause reduction of the tumors in those animals. THE JOURNAL[13] has called attention to the lack of adequate information by which to judge the effectiveness of "KR serum" and has reviewed[14] a subsequent report issued by two Philadelphia investigators seeking to confirm the results of the Russian observers. THE JOURNAL points out that the observations of the American researchers did not confirm the Russian claims and states, "From these negative results the Philadelphia investigators conclude that the alleged 'endotoxin' of T. cruzi does not at present hold out much promise in practical clinical therapy."

### "AUTOVACCINATION"

THE JOURNAL[13] also called attention to the need for authoritative scientific information regarding the use of a method of autoinocculation of human cancer reported by another Russian observer, Krasheninnikov, based on previous observations by Besredka that a certain degree of immunity sometimes developed to intradermal transplants of certain cancerous tumors in animals. Although it was reported that this method as used by the Russian observer had resolved the tumors in 2 patients with stomach cancer treated with transplants of the patient's own tumor into the skin of the abdomen, an American physician has indicated that such results are open to question.[15] The latter pointed out that his own previous observations made with Besredka on the use of the method in human beings gave unfavorable results and that the transplants led only to the establishment of another tumor and thus spread the disease.

Other observers[16] have previously reported regression of human skin cancer in a small preliminary series of patients following intradermal injections of tissue extracts from human spleen or liver, but have withheld judgment as to the curative value of this form of treatment until patients have been observed for at least five years.

### CHYMOTRYPSIN

Another unestablished theory based on the thesis that all cancer is of a trophoblastic nature, such as chorionepithelioma, has been advanced by Krebs and his co-workers.[17] This group has also reported encouraging results from the use of injections of crystalline chymotrypsin, an enzyme of the pancreas, in the treatment of a patient with advanced cancer,[18] although there is lacking adequate proof to connect the theory with the use of the enzyme as a form of treatment for the disease. On the basis of the same theory, another group, Beard and his co-workers,[19] have proposed a test for cancer involving bioassay of chorionic gonadotropin in the urine. This test as an accurate method for the detection of cancer is open to serious question; yet it has been widely publicized in an article appearing in the *Readers' Digest* for August 1947. It has also received other publicity, as the accompanying reproduction of one statement:

CANCER
Is CANCER in any part of your body?
BREAST,LUNG,STOMACH,KIDNEY,LIVER,CHEST,
NECK,THROAT,HEAD,LIMBS, or
INTERNAL ORGANS?
A Labatory URINE-TEST will show.
Labatory Analysis is done by the following Doctors
Howard H. Beard, Ph.D.
Albert B. Katz, Ph.D.
C. M. Wylie, Ph.D.
This new method is less painfull than a Surgeons Knife.
CANCER in the early stage can be cured
with CHYMOTRYPSIN
and shall be administrated by your PHYSICIAN.
Urine-test are by appointment only.
Hours 2-3 p. m. Exept Saturday and Sunday.
CANCER — — DIVISION.
OF
MASSACHUSETTS SPEECH CLINIC
16 CENTRAL AVENUE
SUITE 419
LYNN, MASS.

Information received by way of inquiries further indicates that the speech clinic publicizes the test on a commercial basis for a fee of $200 per person. The proponents of the Krebs theory, however, have denied all responsibility for this publicity and renounce the claim that chymotrypsin is a cure, claiming only that chymotrypsin is a "palliative in human cancer." As yet, evidence definitely to establish its value either as a palliative or cure has not been presented. Both the proposed urine test and the method of treatment must for the present be considered highly experimental, and, until proved to be of some definite value in cancer, the publicity given to either procedure is, to say the least, unfortunate.

The foregoing examples of unestablished remedies for cancer serve to emphasize the false hope that is frequently stimulated by too early and too enthusiastic efforts to publicize the "news" of unproved methods of treatment. The cry of "wolf" once too often could easily create indifference to an announcement of a truly effective remedy for advanced cancer when such a goal is ultimately realized.

### CONCLUSION

The Council emphasizes the need for caution in the premature adoption of new theories or use of unproved treatments proposed for cancer and issues this report in condemnation of the numerous fraudulent remedies for the disease and the early publicity of unestablished remedies. When truly improved methods for the treatment of cancer are found, it seems self evident that these will quickly find wide application to all victims of cancer without the advertising used to promote the sale of cancer nostrums.

# Council on Physical Medicine

## REPORTS OF THE COUNCIL

*The Council on Physical Medicine has authorized publication of the following reports.* HOWARD A. CARTER, *Secretary.*

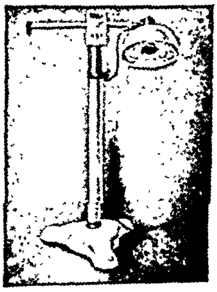
### LIFE LITE THERAPEUTIC LAMP, MODEL H-11, ACCEPTABLE

Manufacturer: Ultra Violet Products, Inc., 5205 Santa Monica Boulevard, Los Angeles 27.

The Life Lite Therapeutic Lamp, Model H-11, is a dual purpose lamp ("two in one") consisting of (1) a source of ultraviolet radiation in the form of a high potential, low pressure "cold quartz" mercury arc lamp and (2) a source of infra-red radiation principally of wavelengths 15,000 to 150,000 angstroms.

These two therapeutic elements are fixed in a hemispherical reflector that is supported on the end of an arm and is free to travel horizontally, rotating about the axis of the arm. This arm is mounted on a substantial base having a vertical telescoping tube that permits adjustment in height ranging from approximately 80 to 150 cm. (32 to 59 inches), measured from the floor to the rim of the reflector, when it is directed downward.

The weight of the lamp is given as 20 Kg. (43 pounds). The packed weight for domestic shipment is 34 Kg. (75 pounds) and for foreign shipment 43 Kg. (95 pounds). It is designed to operate on 120 volt alternating current. When both the ultraviolet and the infra-red elements are in use, the power drawn amounts to approximately 370 watts.



Life Lite Therapeutic Lamp, Model H-11

The Council considered results of mechanical, electrical, radiometric and physiologic tests on this lamp and concluded that mechanically and electrically the device is stable and well constructed, and that there is no danger of electrical shock or thermal burns so long as the parts are unbroken or the unit is not taken apart.

The Council considered further extensive data on: (1) the ultraviolet emitted by this lamp, with power input ranging from 19 to 31 watts (105 to 130 volts); (2) the variation of ultraviolet intensity with distance from the burner, and (3) the variation in intensity along a line perpendicular to the axis of the central beam. The radiometric measurements indicated that approximately 90 per cent of the biologically effective ultraviolet radiation of wavelengths 3,132 angstrom units and shorter emitted by this lamp is in the wave band at 2,537 and that, at the Council's specified distance of 61 cm. (24 inches) from the plane of the rim of the reflector, with the lamp operating on 120 volts (25 watts), the intensity is close to 150 microwatts per square centimeter. This is about four times the minimum intensity stipulated in the Council's minimum requirements for acceptance. Since this can be calculated to produce a minimal perceptible erythema on the untanned skin of average pigmentation in about four minutes, it is in satisfactory agreement with the physiologic findings in the report.

---

[17] Correspondence: Pathology of the Trophoblast, J. A. M. A. **131**: 1527 (Aug. 31) 1946. Gurchot, C.; Krebs, E. T., Jr., and Krebs, E. T.: Growth of Human Trophoblast In Eye of Rabbit: Its Relationship to the Origin of Cancer, Surg., Gynec. & Obst. **84**: 301-311 (March) 1947.

[18] Krebs, E. T.; Krebs, E. T., Jr., and Gurchot, C.: Skeletal Changes Associated with the Use of Crystalline Chymotrypsin in an Apparently Radio-Resistant Growth, M. Rec. **160**: 479 (Aug.) 1947.

[19] Beard, H. H.; Halperin, B., and Libert, S. A.: Effect of Intraperitoneal Injection of Malignant Urine Extracts in Normal and Hypophysectomized Rats, Science **105**: 475-477 (May 22) 1947.

The 350 watt infra-red element, consisting of a flat disk about 9 cm. (3.6 inches) in diameter and located at the center of the ultraviolet generator, delivered tolerance heat at 12 inches. The infrared heater complies with the Council's requirements.

The Council on Physical Medicine voted to include the Life Lite Therapeutic Lamp, Model H-11, in its list of accepted devices.

## WESTERN ELECTRIC 4CA AUDIOMETER ACCEPTABLE

Manufacturer: Western Electric Company, 120 Broadway, New York 5.

The Western Electric 4CA Audiometer is of the phonograph type and is designed to test auditory acuity for numbers by the use of calibrated records available through Western Electric dealers. The instrument incorporates a one stage vacuum tube amplifier which is capable of activating as many as forty telephone receivers. Thus the instrument is of the type adaptable to group screening for the purpose of isolating persons with losses of hearing. It has the following accessories:

4CA receiver tray with 10 receivers
4CA receiver tray case for holding 3 trays of receivers
KS-10087 test record for 2 digit numbers
KS-10075 calibration record
Bagshaw's Brilliantone needles
KS-677650-1 hearing test sheets
KS-677651-1 master sheets for checking

The instrument weighs 10.4 Kg. (23 pounds); its shipping weight is 13.2 Kg. (29 pounds). The dimensions of the case are 22 by 37 by 66 mm. (8½ by 14½ by 26 inches).

The 4CA Audiometer uses one, two, three or four trays of ten magnetic receivers with head bands and receivers. One tray is carried in the audiometer case. Additional trays are carried in a matching receiver tray case.

When in its carrying case the instrument is easily transportable and possesses a desirable degree of ruggedness. The phonograph motor is spring driven to make it independent of local power supply or availability of convenient electrical outlets. There is electronic amplification, and a meter built right into the instrument which serves the double purpose of allowing battery voltages to be measured and of allowing the amplifier output to be set at the level requisite for standardized testing. Dry cells of substantial size which will last a normal school year furnish the A and B supply for the amplifier. In order to replace them it is necessary to unscrew the turntable mounting panel. Stopping the turntable automatically turns off the amplifier; this feature minimizes the danger of exhausting the batteries when tests are not actually being given.

The receiver trays are connected in series and the output of individual receiver is the same, regardless of the number of trays used.

Each subject wears a single headphone. The receiver unit is easily removable from its plastic shell in the event of need of replacement.

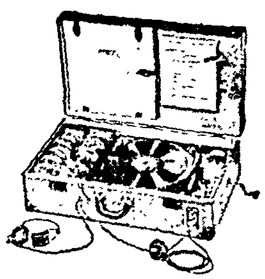
An instruction sheet is mounted in plastic in the top of the audiometer case. A circuit diagram is included under the baseplate for the phonograph.

Two records are supplied with the instrument. The first record is used to calibrate the instrument and to check the condition of the individual receivers. It presents a continuous warbling note.

The second record is designed especially for use with Western Electric 4 type audiometers. It presents numbers at descending intensity levels (with two digits to a level and 3 decibels as the gap between levels). The record covers the range of hearing (in sensation units as compared with normal threshold for numbers) from plus 30 to minus 3 decibels when played on a properly calibrated instrument.

The 4CA was designed to permit school systems now using the 4A and 4C Audiometers, in need of additional equipment, to purchase a 4CA Audiometer with assurance that the test procedure with the children and the scoring of the papers are also identical.

The specimen submitted for examination was given a field trial to determine three things: namely, (1) the ease with which the instrument could be operated by an experienced tester; (2) the credibility of the test results yielded by the instrument, and (3) the stability of the instrument's calibration adjustment over periods of ordinary use. In all three respects the apparatus was found suitable for group testing.



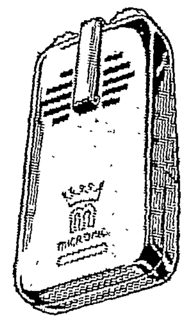
Western Electric 4CA Audiometer.

The Council on Physical Medicine voted to include the Western Electric Audiometer, Model 4CA, in its list of accepted devices.

## MICRONIC MODEL 101 (MAGNETIC RECEIVER) HEARING AID ACCEPTABLE

Manufacturer: Micronic Company, 727 Atlantic Avenue, Boston 11.

The Micronic Model 101 Hearing Aid is the counterpart to a model previously accepted by the Council. The previous model had a crystal receiver; the present model has a magnetic receiver. While no changes have been made in the wiring of the circuit, minor changes have been made in the chassis. The silver-colored metal case contains microphone, amplifier and batteries. The outside dimensions are 105 by 57 by 27 mm. (4⅛ by 2¼ by 1 1/16 inches) exclusive of the clip in front of the microphone. The entire instrument, with batteries, weighs about 185 Gm. (6½ ounces). The A-battery is of the zinc-carbon type; the B-battery, likewise of the zinc-carbon type, gives 22.5 volts. The batteries are easily replaced. The instrument appears to be sturdily constructed; the following are results of a performance test:



Micronic Hearing Aid Model 101 (Magnetic Receiver).

| | | Articulation Scores | | |
|---|---|---|---|---|
| Subject | Acoustic Gain | Micronic | Reference | Difference |
| A | 49 db. | 85% | 80% | + 5% |
| B | | 78% | 77% | + 1% |
| C | 42 db. | | | |
| D | | | | |
| Average | 46 db. | | | + 3% |

The acoustic gain is thus well above the minimum of 30 decibels required by the Council's specifications; the tabulated data show that the articulation of the instrument is slightly better than that of the reference instrument used.

The Council on Physical Medicine voted to include the Micronic Model 101 (Magnetic Receiver) Hearing Aid in its list of accepted devices.

SATURDAY, JANUARY 8, 1949

## THE DIAGNOSIS OF INFLUENZA

The Commission on Acute Respiratory Diseases[1] has completed studies carried on at Fort Bragg and Camp Mackall of the 1943 epidemic of influenza A. The results of this investigation have been published in a series of eight papers in the November 1948 *American Journal of Hygiene.* The Commission reviews the clinical features as well as the less well known methods of laboratory diagnosis of influenza. The "typical" clinical features are usually considered to be sudden onset of fever, muscular aching, prostration and various signs of inflammation of the respiratory tract. High morbidity rates, wide geographic extent and a sharp increase in pneumonia mortality characterize epidemics, many of which during the past century have been recognized on the basis of these criteria. Nevertheless, it is often difficult to differentiate the clinical and epidemiologic characteristics of influenza from various other forms of respiratory disease.

Since the causative agents of influenza were discovered and laboratory methods of diagnosis have been developed, it has been shown that the influenza viruses may produce not only "clinical" cases but numerous mild atypical illnesses and obscure infections. The proportions of clinical cases which have been confirmed by serologic methods have varied so widely that doubt has been cast on the specificity of influenza epidemics.

Stuart-Harris, Andrewes and Smith[2] studied outbreaks of respiratory disease at military depots in Great Britain and reported differences between the clinical patterns of cases occurring during epidemics of influenza and cases studied during epidemics of noninfluenzal "febrile catarrh." Francis[3] in the United States reported similar observations during the 1936-1937 epidemic of influenza A. In subsequent studies, a definite distinction was not always possible. Thus, some investigators have come to question the existence of a characteristic clinical pattern in influenza A.

A major objective of the present study of the Commission on Acute Respiratory Diseases was to reassess the reliability of clinical, epidemiologic and laboratory methods for diagnosing influenza. During the studies at Fort Bragg, clinical observations were made in a group of 2,000 recruits among whom an epidemic of influenza A was followed by an epidemic of undifferentiated acute respiratory disease. Identical methods of examining patients and recording clinical data were employed in both outbreaks. When the two types of cases were compared in the aggregate, definite clinical differences were observed. Sudden onset, high grade fever, severe constitutional symptoms and involvement of the nasal mucosa were associated more frequently with influenza A than with undifferentiated acute respiratory disease. Other evidence of inflammation of the respiratory tract, particularly sore throat, was observed more often in acute respiratory disease. When the illnesses were diagnosed as influenza A or acute respiratory disease by serologic methods, the differences observed supported the concept of influenza as a separate clinical syndrome. When an attempt was made to differentiate the two diseases in the individual patient by clinical methods alone, however, the accuracy of clinical diagnosis was hardly better than could have been achieved by chance. The "classical" symptom complex was observed in only half of the patients with serologic evidence of influenza A, while numerous patients with acute respiratory disease showed the same clinical picture.

An outstanding feature of the 1943 epidemic in the Army was the simultaneous occurrence of the disease among both seasoned men and recruits. It was the only widespread epidemic of acute respiratory disease observed among seasoned men at Fort Bragg during the period 1942 to 1945. Among recruits, however, laboratory procedures were usually necessary to determine the cause of an epidemic. The occurrence of an epidemic of acute febrile respiratory disease among organizations composed of seasoned men is strong presumptive evidence of the presence of influenza. An epidemic which is confined to recruits, however, is more likely to be undifferentiated acute respiratory disease.

Confirmation of the clinical diagnosis of influenza may be obtained by the demonstration of a rise in the antibody titer of serum collected during convalescence as compared with serum obtained early in the

A-CC-No·64

illness and by isolation of virus from nasal or pharyngeal washings. A comparative study of four serologic methods for determination of antibodies indicated that the agglutination-inhibition test gave results which were comparable to those obtained with complement fixation and mouse neutralization. In contrast, egg neutralization was the least sensitive test and the most difficult one to perform. The agglutination-inhibition test is based on the fact that influenza viruses agglutinate chicken red blood corpuscles and that this capacity is specifically inhibited by immune serum.[4]

Less than a fourfold antibody response formerly was considered within the limits of experimental error in serologic tests for influenza A. During these studies of the 1943 epidemic, however, the frequent occurrence of twofold increases in titer in the agglutination-inhibition test was considered indicative of influenzal infection.

The specificity of the agglutination-inhibition test appears to vary with the particular strain of virus which is used as antigen. In this epidemic, slight differences were observed between tests performed with the PR8 virus and a locally isolated CRA strain. Epidemiologic evidence indicated that the routine use of the PR8 virus adequately measured the occurrence of influenza. Diagnostic increases in antibody were observed in 90 per cent of the cases among seasoned troops and in 80 per cent of the epidemic cases which occurred in late November and early December among recruits.

The studies at Fort Bragg indicated that the agglutination-inhibition test was a specific and satisfactory procedure for the diagnosis of influenza A in the 1943 epidemic. The agglutination-inhibition technic provided a method for the laboratory diagnosis of influenza that was sufficiently accurate to permit a reliable description of the clinical and epidemiologic behavior of the disease during this epidemic. This finding generally accords with the experience of others.

A comparison of methods for isolating the influenza virus was carried out by the use of embryonated hens' eggs, ferrets and hamsters. Conflicting evidence was secured with regard to the persistence of virus in patients, depending on the method of detection. By inoculation of embryonated hens' eggs, virus was found most frequently during the first three days of illness and occasionally until the sixth day. By the use of ferrets and hamsters, essentially similar results were observed during the first six days of illness but, in addition, evidence of virus was also found in throat washings collected on the seventh, ninth, fifteenth and thirty-fifth days. However, the question of the existence of convalescent carriers of influenza must await further confirmation.

## STREPTOMYCIN-RESISTANT TUBERCULOSIS

One of the handicaps in streptomycin treatment of tuberculosis arises from the apparent rapidity with which tubercle bacilli acquire resistance to this drug. Patients under treatment with streptomycin may at times discharge tubercle bacilli several thousand fold more resistant to streptomycin than the usual strains. This acquired streptomycin tolerance has been studied in detail by Pyle[1] of the Mayo Clinic.

Pyle found that cultures of tubercle bacilli isolated from patients prior to streptomycin therapy are composed of bacterial cells which differ greatly in their streptomycin tolerance. From this he proposes the theory that the more susceptible organisms in a tuberculous lesion are retarded in their growth, thus allowing overgrowth by the more resistant variants. As soon as a predominantly resistant population is established the tuberculous process would become refractory to therapy with streptomycin.

This selective adaptation has been subjected to detailed clinical study by Youmans and Williston[2] of Northwestern University. They prepared Harrold's glycerin egg agar slants containing serial dilutions of streptomycin (1,000 to 0.095 microgram per cubic centimeter). Freshly isolated cultures from tuberculous patients were finely emulsified and heavily inoculated on each of the serial dilutions. The slants were then incubated and examined at weekly intervals for six weeks.

At the end of two weeks all cultures showed a profuse growth on the control or streptomycin-free slant. There was also growth on some of the slants containing the lower concentrations of streptomycin. As the time of incubation lengthened, growth would usually appear on tubes containing the next one or two higher concentrations. These later growths usually consisted of a few scattered colonies. Examination after four weeks' incubation often revealed single isolated colonies on still higher concentrations. These results confirmed Pyle's report that cultures of tubercle bacilli are not composed of cells with a uniform sensitivity to streptomycin.

Of the 57 recently isolated cultures used in their study 25 or 43.5 per cent yielded streptomycin-resistant variants. Twelve of these were resistant to concentrations as high as 100 micrograms per cubic centimeter and 5 to as high a concentration as 500 to 1,000 micrograms per cubic centimeter. Of the 14 cultures isolated from patients before streptomycin therapy was initiated, 9 or 64.3 per cent yielded refractory bacilli. Of the 43 cultures obtained from patients following the institution of streptomycin therapy, streptomycin-resistant variants were isolated from only 37.1 per cent. This lower percentage is seemingly at variance with expectations for Pyle's theory of selective dominance.

[2] Youmans, G. P., and Williston, E. H.: Proc. Soc. Exper. Biol. & Med., **68**: 458 (July-August) 1948.

This research is being continued in the hope of determining whether or not in patients who show streptomycin-resistant variants prior to the administration of streptomycin streptomycin-refractory tuberculosis is likely to develop. Whether or not acquired resistance to streptomycin is accompanied by an increase or a decrease in virulence will also be determined. A decreased virulence might be predicted from current bacteriologic theory.

## Current Comment

### THE VALUE OF A DOCTOR

In a recent schedule of United States Civil Service examinations announcement is made of an examination for a medical officer at a salary of $4,479 to $6,235 per year. In the same announcement there is offered for an agricultural research scientist up to $8,509, for a geographer up to $10,305, chemist $7,432 and astronomers, clinical psychologists and geologists the same. An oceanographer can get up to $10,305. Oh! for a life on the ocean wave!

### TOOTHBRUSHES

Americans use more toothbrushes than most of the rest of the world, but even in the United States a survey made some years ago showed that less than one half the people have a toothbrush which they use regularly. There is evidence that very few persons have two toothbrushes which they alternate at various times during the day. While the scientific evidence in support of brushing the teeth as a means of preventing caries or other disturbances is not too profuse or too well established, the use of the brush has met with almost universal approval by hygienists, dentists and physicians. Recently a survey[1] was made of the average use of toothbrushes in the American home. New toothbrushes were offered to a selected sampling of American families who had sent in their toothbrushes then in use. Over 8,000 toothbrushes were received, and more than 6,500 were found to be inadequate and unsatisfactory for a variety of reasons. These included bent or broken bristles, matted bristles or unsatisfactory condition. Almost 2,000 families participated. The average was 4.2 brushes per family. Since there were slightly less than 4 persons per family, it could be assumed that each member of the family had a toothbrush, but examination of the toothbrushes indicated that many of them were being used for other purposes than for brushing the teeth. More than 80 per cent of the brushes were found to be in need of replacement because they could no longer be effective implements in hygiene of the mouth or because their condition was such that they might injure dental tissue. Almost 2,000 toothbrushes were found to be unsatisfactory because of caked dentifrices and food debris at the base of the bristles. Apparently there ought to be some sort of routine inspection and rehabilitation of toothbrushes like that given to motor cars, oil heaters and other domestic devices. The care of a brush of any kind should include thorough cleansing and drying after use and especially when debris accumulates.

### WORKMEN'S COMPENSATION

For some time, one of the functions of the Council on Industrial Health has been the study of the complicated ramifications of medical relations in workmen's compensation. During the past few years, it has been evident that such problems needed the consideration of those whose experience might be of additional help to the Council's Committee on Workmen's Compensation. Accordingly, Dr. C. O. Sappington, Chicago, has been appointed as executive director of this Committee. Consultants are also being appointed representing the administrative, legal, insurance and technical aspects of workmen's compensation. The directors of the Bureau of Legal Medicine and Legislation and the Bureau of Medical Economic Research have been invited to serve as members of this consulting group. Projected activities will include field visits to industrial commissions and insurance organizations, attendance at appropriate meetings, preparation of educational material for publication and distribution, consultation services to state and other medical groups, collection of data for special presentation to the profession and the necessary steps to improve treatment of compensable disability, evaluation of disability and medical testimony. The work of the committee is necessarily long range. A few projects may be developed rapidly; others will take time. Medical activity in workmen's compensation can be improved in many ways, and this new approach should produce definite and measurable results.

### TASTE BLINDNESS AND DIABETES IN IDENTICAL TWINS

Segall[1] describes the identical genetic constitution of a set of identical twin girls of Jewish parentage. The children both became diabetic between the ages of 3 and 4, had similar bizarre neurologic lesions, mental deficiency and pes cavus. Additionally, both children were taste blind for phenylthiocarbamide (PTC). Neurologic lesions described in the twins emphasized a pattern which existed in the mother at the time of birth. Nondiabetic brothers of the twins were tasters for PTC. Study of the twins emphasized a previously suggested relationship between PTC taste blindness and diabetes. Both these conditions have been assumed to be inherited as recessive mendelian characters. Terry and Segall,[2] in previous study of 680 diabetic and nondiabetic persons, demonstrated a 15.3 per cent greater taste blindness among the diabetic group, indicating an apparently significant statistical difference. A true association was believed to exist even though testing for taste blindness lacks much procedural exactness.

# ORGANIZATION SECTION

## Official Notes

### APPLICATIONS FOR SPACE IN SCIENTIFIC EXHIBIT AT ATLANTIC CITY TO CLOSE JANUARY 15

The program for the Scientific Exhibit at the Atlantic City Session is progressing rapidly. The commemoration of the Fiftieth Anniversary of the Scientific Exhibit will be marked by a group of special exhibits, including pathologic specimens similar to those shown in 1899, as well as other material of a historical nature. The Special Exhibit on Fractures will be a summation of more than twenty years' activity in the presentation of this feature. Each of eighteen Sections of the Scientific Assembly will have groups of exhibits dealing with the various specialties and much excellent material is in prospect.

Several other proposed features include clinical demonstrations with patients. Motion pictures will be shown in two large rooms adjacent to the exhibits.

Applications for space in the Scientific Exhibit, as well as applications for time on the motion picture program, will close on January 15. Applications should be sent to the Section Representatives or to the Director, Scientific Exhibit, American Medical Association, 535 N. Dearborn St., Chicago 10, Ill.

### PROGRAM OF ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

**To be held in the Red Lacquer Room, Palmer House, Chicago, February 6, 7 and 8, 1949**

#### *ADVISORY BOARD FOR MEDICAL SPECIALTIES*

SUNDAY MORNING, FEBRUARY 6, 9:00 A. M.—12:30 P. M.

Round Table Discussion: *The Effects of the Specialty Boards on American Medicine.*

Participants to be announced. They will include representatives of medical schools, hospitals, the general public, the armed services, the general practitioner, the specialty boards and the Council on Medical Education and Hospitals of the American Medical Association. The formal program will be followed by a period devoted to questions and general discussion from the floor.

Room To Be Announced

#### COUNCIL ON MEDICAL EDUCATION AND HOSPITALS, AMERICAN MEDICAL ASSOCIATION

MONDAY MORNING, FEBRUARY 7, 9:30 A. M.

H. G. WEISKOTTEN, M.D., *Presiding*

*Address of the Chairman*
H. G. WEISKOTTEN, M.D., Chairman, Council on Medical Education and Hospitals, American Medical Association

*Economics of the Hospital System*
ELI GINSBERG, PH.D., Professor of Economics, Columbia University and Director of the New York State Hospital Study

*Utilization of Regional Hospitals for Medical Education*
CHARLES F. WILKINSON JR., M.D., Director, Division of Medicine, W. K. Kellogg Foundation and Assistant Professor of Internal Medicine, University of Michigan Medical School

*The World Medical Association and Medical Education*
LOUIS H. BAUER, M.D., Secretary General, World Medical Association

*Classification Policies of Selective Service System*
COL. RICHARD H. EANES, M.C., Chief Medical Officer, Selective Service System

MONDAY AFTERNOON, FEBRUARY 7, 2:00 P. M.

H. G. WEISKOTTEN, M.D., *Presiding*

*The Relationship of the United States Public Health Service to Medical Education*
LEONARD A. SCHEELE, M.D., Surgeon General, United States Public Health Service

*A Preliminary Consideration of the Program of the U. S. Public Health Service for the Improvement of Teaching in "Cancer"*
SAMUEL C. HARVEY, M.D., Professor of Oncology, Yale University School of Medicine

*Pediatrics in the Medical Curriculum*
JOHN MCK. MITCHELL, M.D., Dean, University of Pennsylvania School of Medicine

*Psychiatry in Medical Education*
WILLIAM MALAMUD, M.D., Professor of Psychiatry, Boston University School of Medicine

#### THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

MONDAY EVENING, FEBRUARY 7, 7:00 P. M.

*FEDERATION DINNER*

*Observations of Medical Conditions in Europe*
ROSS L. SENSENICH, M.D., President, American Medical Association
Crystal Room

TUESDAY MORNING, FEBRUARY 8, 9:30 A. M.

EARLE G. JOHNSON, M.D., *Presiding*

*Address of the President*
EARLE G. JOHNSON, M.D., Nebraska Bureau of Examining Boards

*Medical Education in Denmark, Norway and Sweden*
ALBERT B. SABIN, M.D., Professor of Research Pediatrics, University of Cincinnati College of Medicine

*Medical Education in Poland and Finland*
EUGENE B. FERRIS JR., M.D., Associate Professor of Medicine, University of Cincinnati College of Medicine

*Foreign Medical Graduates*
CREIGHTON BARKER, M.D., Secretary, Connecticut Medical Examining Board

*British National Health Act*
MORRIS FISHBEIN, M.D., Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

TUESDAY AFTERNOON, 12:30 P. M.

*FEDERATION LUNCHEON*

Room To Be Announced

TUESDAY AFTERNOON, FEBRUARY 8, 2:00 P. M.

EARLE G. JOHNSON, M.D., *Presiding*

*Panel Discussion on:*
Licensure of Hospital Residents
Osteopathic and Medical Practice
Foreign Medical Graduates
National Licensing Board
New Licensure Legislation

*Members of the Panel:*
J. EARL MCINTYRE, M.D., Secretary, Michigan Board of Registration in Medicine
GEORGE W. COVEY, M.D., Nebraska Bureau of Examining Boards
ALBERT B. SABIN, M.D., Cincinnati
EUGENE B. FERRIS, M.D., Cincinnati
CREIGHTON BARKER, M.D., New Haven, Conn.
GEORGE H. RUHLAND, M.D., District of Columbia Commission on Licensure
J. W. HOLLOWAY JR., Director, Bureau of Legal Medicine, American Medical Association

TUESDAY AFTERNOON, FEBRUARY 8, 4:00 P. M.

Business Session

## NATIONAL CONFERENCE ON RURAL HEALTH

The fourth annual meeting of the National Conference on Rural Health will take place at the Palmer House Feb. 4 and 5, 1949. The following program has been prepared:

### FRIDAY MORNING

8:00 A. M. *Registration*
Red Lacquer Room

9:00—9:05 A. M. *Address of Welcome*
George F. Lull, M.D., Secretary and General Manager, American Medical Association

9:05—9:15 A. M. *Purpose of Conference*
F. S. Crockett, M.D., Chairman, Committee on Rural Health, American Medical Association

9:15—9:55 A. M. *Health Programs of National Farm Organizations*
Mrs. J. Laning Taylor, Educational Director, The National Cooperative Milk Producers' Federation, Washington, D. C.
Joseph W. Fichter, Master, Ohio State Grange, Columbus, Ohio.
Mrs. Gladys T. Edwards, Director of Education, Farmers Educational and Cooperative Union of America, Denver, Colorado
H. E. Slusher, Chairman, Medical Care Committee, American Farm Bureau Federation, Jefferson City, Missouri

9:55—10:15 A. M. *A State Rural Health Committee in Action*
J. S. De Tar, M.D., Council Member, Committee on Rural Health, Michigan State Medical Society, Milan, Michigan

10:15—10:35 A. M. *Environmental Hygiene*
Ernest E. Stebbins, M.D., Professor of Public Health, Johns Hopkins University School of Public Health, Baltimore

10:35—10:55 A. M. *Animal Diseases Affecting Humans*
H. B. Mulholland, M.D., Committee on Rural Health, American Medical Association, Charlottesville, Virginia

10:55—11:10 A. M. *Intermission (Film)*

11:10—11:30 A. M. *Nutrition and the Soil*
Glen W. Bunting, Manager, Central Farmers' Fertilizer Company, Chicago

11:30—12:00 A. M. *Health Education and Community Responsibility*
Aubrey Gates, Associate Director, Cooperative Extension Work, College of Agriculture, University of Arkansas, Little Rock

12:00—12:30 P. M. *The General Practitioner in Rural Practice*
Ward Darley Jr., M.D., Executive Dean, Health Sciences and Services, University of Colorado School of Medicine, Denver

### PALMER HOUSE, FRIDAY AFTERNOON

Round Table Discussions

2:00—5:00 P. M.

Section I *Cooperative Health Programs for Rural Areas*
- a. Local health units
- b. Local health councils
- c. Cooperative hospitals

Chester Starr, Chairman
Mrs. Dora Barney, Co-Chairman
John W. Ferree, M.D., Discussion Leader

Section II *Environmental Hazards*
- a. Animal diseases affecting human beings
- b. Farm accidents
- c. Environmental hygiene

D. G. Miller, M.D., Chairman
C. W. Kruse, Co-Chairman
Maynard Coe, Discussion Leader

Section III *Health Education—Individual and Community Responsibility*
Roger Corbett, Chairman
Elin Anderson, Co-Chairman
Paul Miller, Discussion Leader

Section IV *The General Practitioner in Rural Practice*
- a. Preparation for Rural Practice
- b. Facilities
- c. Other factors

Franklin Murphy, M.D., Chairman
Lester G. Evans, M.D., Co-Chairman
Mrs. Haven Smith, Discussion Leader

Section V *Nutrition and the Soil*
W. A. Albrecht, Chairman
Jonathan Forman, M.D., Co-Chairman
Glen Bunting, Discussion Leader

### RED LACQUER ROOM, SATURDAY MORNING

9:30 A. M. *Reports of Round Table Committees and Discussions*

1:00 P. M. *Luncheon*
Speakers:
Introduction of W. L. Pressly, M.D., General Practitioner of the Year, Due West, South Carolina
Roscoe L. Sensenich, M.D., President, American Medical Association, South Bend, Indiana
Dr. John O. Christianson, Superintendent of the School of Agriculture, University of Minnesota, St. Paul

## Washington Letter

*(From a Special Correspondent)*

Jan. 3, 1949.

### Voorhees Report Urges Sweeping Federal Medical Reforms

Culminating nearly a year's study, the Voorhees Report was issued December 26 by the Hoover Commission, recommending a large number of drastic changes in the federal government's medical establishment. All of its widely scattered services are affected by the proposals, which are expected to be incorporated in the Hoover Commission's final report on reorganization of the government's executive branch which is to be submitted to Congress. Tracy S. Voorhees, Assistant Secretary of the Army, is chairman of the committee and Dr. Edward D. Churchill, professor of surgery at Harvard University Medical School, vice chairman. Ten of the other fourteen members of the committee are doctors of medicine.

The investigators recommended:

Establishment of a cabinet-status federal department encompassing health, education and welfare activities, with a National Bureau of Health that would administer all general hospitals of the Army, Navy, Veterans Administration and U. S. Public Health Service. The armed services would be left only with one teaching hospital each, overseas hospitals and those station hospitals within the continental limits which were too isolated to make inclusion in the merger practical.

Transfer of all medical functions of the Veterans Administration, including outpatient services now performed at regional and branch offices, to the proposed National Bureau of Health. The latter also would take over operation of St. Elizabeths Hospital, 7,000 bed federal mental institution in the District of Columbia.

Greater utilization by the federal government of private and voluntary hospital facilities throughout the country for care of veterans, servicemen's dependents and other charges, on a reimbursable basis.

Congressional action to decide whether the government should extend medical and hospital care to all veterans, irrespective of financial circumstances; solely to service-connected patients, or to the latter plus non-service-connected patients who are economically unable to pay for private care.

Appointment of a deputy to the Secretary of Defense who would supervise medical services in the armed forces. (Secretary Forrestal recently named Charles Proctor Cooper to fill this newly created position and to be chairman of the Armed Forces Medical Advisory Committee, whose first meeting is expected to be held in January.)

Transfer of Food and Drug Administration to the National Bureau of Health's public health division, whose main functions would be administration of grants-in-aid, operation of a clearing house of information on public health activities and enforcement of laws and regulations on interstate commerce in foods, drugs and medicines.

Retention by the Children's Bureau of its present medical, health and grant-in-aid activities because the Bureau "should function as a staff unit directly responsible to the secretary of the proposed department, rather than having its health and other functions split and united with the major proponent units of the department."

Creation of a coordinating committee on nonmilitary medical research comprising representatives of the National Bureau of Health's research and training division, the Atomic Energy Commission and the Department of Agriculture. Also, establishment of an Inter-Agency Committee on Medical Sciences, representing both military and nonmilitary branches of the federal government, whose primary concern would be with appraisal and allocation of government support to nonfederal research institutions.

Transfer to the proposed research and training division of all operations now performed by the National Institutes of Health (research arm of the U. S. Public Health Service). The division would operate and control the $40,000,000 Clinical Research Center now under construction at suburban Bethesda, Md.

Establishment of a new federal career medical service whose nucleus would be the present personnel of the Veterans Administration hospitals, the commissioned personnel of the U. S. Public Health Service and all medical professional personnel employed under Civil Service. The U. S. commissioned officers of the U. S. Public Health Service would have the option of joining the new service or continuing in present status, "but no new commissions should be issued."

Institution by the U. S. Public Health Service of a study to determine financial needs of the nation's medical schools and recommend how they should be met. "Care must be taken in granting aid to maintain the professional independence and the initiative of the schools. Also the aid should be given in such a way as to increase the output of trained personnel especially in the areas where there are acute deficiencies."

Unification of medical supply procurement.

Over-all coordination of federal organizations in the medical field by the Bureau of the Budget, assisted by an advisory committee, unless a special agency for this purpose is established in the Office of the President.

"We have attempted to outline a method which we hope will correct the extravagances resulting from the present series of unrelated projects and weld these together into an integrated orderly whole," says the Voorhees Report. "With such an organization, staffed by outstanding personnel, it should be possible to utilize our unequaled medical resources to the maximum and by intelligent planning take steps which will make us a healthier and stronger nation."

### Secretary Krug Makes Public Alaskan Health Report

A report urgently recommending correction of Alaska's nine "most urgent" health problems was made public December 9 by Secretary of Interior Julius A. Krug. The report was based on a territorial survey conducted by an American Medical Association committee composed of Drs. John E. Tuhy of Portland, Ore., chairman, Frank H. Douglass of Seattle, W. Charles Martin of Portland, Austin T. Moore of Columbia, S. C., and David B. Law of Seattle. All but Dr. Law, a dentist, are physicians. Alaska's most serious health problems, said the report, are: (1) high incidence of tuberculosis and inadequacy of treatment facilities; (2) shortage of doctors, nurses and technologists; (3) insufficiency of hospital beds in certain communities and absence of any psychiatric hospital in the entire territory; (4) weak control of preventable and communicable disease, especially venereal infections; (5) lack of good sanitation in towns and villages; (6) frequency of alcoholism, with its social and economic consequences; (7) wide prevalence of eye diseases; (8) shortage of dentists and lack of dental care among the natives, and (9) low standards of housing, education and hygiene among natives, conducive to high disease rates.

The American Medical Association group's report to Secretary Krug, who is titular head of the Bureau of Indian Affairs, recommended construction of additional hospital facilities, higher salaries and other inducements to attract physicians and dentists into the Alaska Native Service, construction of a mental hospital in the Matanuska Valley near Anchorage, improvement of living conditions through housing subsidies and certain other measures.

### Retention of $100 Extra Pay for Military Doctors Indorsed

The Advisory Commission on Service Pay (Hook Commission) recommended retention of the $100 a month inducement pay now received by medical and dental officers of the Army, the Navy and the Public Health Service, in its report on revision of the armed services' pay structure. Secretary Forrestal made the report public in late December. Of the approximately fifty types of special or extra pay now in vogue, retention of only three is recommended: hazardous duty, sea and foreign duty (for enlisted personnel only) and the inducement pay for medical and dental officers. However, this $100 extra per month would be withdrawn from interns, who are now eligible to receive it.

It was recommended by the Hook Commission that, prior to expiration of the law granting extra pay for medical and dental officers, Secretary Forrestal appoint a personnel board to decide whether this extra compensation should be continued or whether recruitment of doctors has reached a level that would justify its being terminated. Meanwhile payment should be continued, said the Hook Commission. It added that medical and dental officers "should be given constructive credit for pay and promotion equal to the number of years—not in excess of four—of recognized postgraduate training, unless such years are already credited by virtue of other provisions of the law."

### Forty-Two Medical Schools Receive Psychiatric Training Grants

Award of $1,498,333 in grants to forty-two medical schools for development or expansion of training in psychiatry for undergraduate medical students has been approved by Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, on recommendation of the National Advisory Mental Health Council. The funds will become available in July 1949. All but five of the grants are for amounts between $34,000 and $37,500 each.

### Houston Naval Hospital Transferred to the Veterans Administration

Veterans Administrator Carl R. Gray Jr. announced transfer to the Veterans Administration of the Navy's 1,000 bed psychiatric hospital at Houston a few days before publication of the Voorhees Report, which advocated the shift. Plans for the Veterans Administration's separate psychiatric hospital, of the same size and which was nearing the construction stage, have been canceled. The transfer will result in a $21,000,000 saving, said Gray, pointing out that it obviates operation of two federal psychiatric institutions across the highway from each other and permits the Veterans Administration to meet needs for 1,000 specialized beds in the Houston area two years earlier than planned.

---

## Coming Medical Meetings

Annual Congress on Industrial Health, Chicago, Drake Hotel, Jan. 18-19. Dr. Carl M. Peterson, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 7-8. Dr. Donald G. Anderson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 4-5. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

---

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

American Society for Surgery of the Hand, Chicago, Jan. 21-22. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

International Post-Graduate Medical Assembly of Southwest Texas, San Antonio, Jan. 25-27. Dr. John J. Hinchey, P. O. Box 2445, San Antonio, Secretary.

Southeastern Allergy Association, Durham, N. C., Washington-Duke Hotel, Jan. 22-23. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia, S. C., Secretary.

Southeastern Surgical Congress, Biloxi, Miss., Jan. 24-27. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Ga., Secretary.

Western Section American Urological Association, Coronado, Calif., Hotel del Coronado, Jan. 17-19. Dr. Adolph A. Kutzmann, 1930 Wilshire Blvd., Los Angeles 5, Secretary.

# GOVERNMENT SERVICES

## NAVY

### FIRST ACTIVE DUTY AS INTERNS

The following lieutenants (jg) in the Medical Corps Reserve have been ordered to their first active duty as interns at civilian medical institutions under the Navy's Medical Training Program. On completion of this training, they will serve at naval activities: Robert K. Bench, Long Beach, Calif., to General Hospital of Fresno County, Fresno, Calif.; Rodger L. Buck, Chicago, to Cook County Hospital, Chicago; William C. Crittenden, Birmingham, Ala., to Grasslands Hospital, Valhalla, N. Y.; Paul T. Drenning, Wayne, Pa., to Huron Road Hospital, East Cleveland, Ohio; Bernard E. Ferrara, Charleston, S. C., to Roper Hospital, Charleston, S. C.; Morton W. Friedman, Los Angeles, to Los Angeles County Hospital; William J. Godfrey, Flushing, N. Y., to Queens General Hospital, Jamaica, N. Y.; James E. Goode, Dallas, Texas, to Scott and White Hospital, Temple, Texas; M. Edwin Green Jr., Harrisburg, Pa., to Temple University Hospital, Philadelphia; Walter B. Grenell, St. Petersburg, Fla., to Cook County Hospital, Chicago; George R. Hatcher Jr., Cleveland, to Grasslands Hospital, Valhalla, N. Y.; William M. Hicks Jr., St. Bernard, Ohio, to Cincinnati General Hospital, Cincinnati; Alfred L. Ingerick, Gallipolis, Ohio, to St. Mary's Hospital, Huntington, W. Va.; Jerrold K. Longerbeam, Redlands, Calif., to Los Angeles County Hospital; Joseph F. Lutz, Bloomfield, N. J., to Newark City Hospital, Newark, N. J.; John R. McCarthy, Chicago, to St. Francis Hospital, Evanston, Ill.; John J. Mezzanotte, Philadelphia, to Nazareth Hospital, Philadelphia; Arthur G. Nelson, Clifton, Texas, to St. Luke's Hospital, Chicago; Robert P. Parker, Seattle, to King County Hospital, Seattle; Harold T. Pruessner, San Antonio, Texas, to Philadelphia General Hospital; Leonard A. Sarnat, Chicago, to Cook County Hospital; Richard C. Stevens, Buffalo, to Huron Road Hospital, East Cleveland, Ohio; William D. Swackhamer, Superior, Ariz., to Charity Hospital of Louisiana, New Orleans; John B. Tully Jr., Bronx, N. Y., to Indianapolis General Hospital, Indianapolis, and Louis W. Wileman, Los Angeles, to State of Wisconsin General Hospital, Madison, Wis.

### POSTGRADUATE INSTRUCTION

The following medical officers have been nominated to receive postgraduate instruction in medical specialties: Lieutenant Commander George W. Deyoe, St. Petersburg, Fla., to instruction in children's orthopedics at Carrie Tingley Hospital for Crippled Children, Hot Springs, N. M.; Lieutenants Walter F. Harrison Jr., Woodhaven, N. Y., to a residency in surgery at the Naval Hospital, Bethesda, Md., and Karl R. Whitney, Sudbury, Mass., to instruction in aviation medicine at the School of Aviation Medicine and Research, Pensacola, Fla., and Lieutenants (jg) Benjamin F. Burns, Harrisburg, Pa., to a residency in obstetrics and gynecology at the Naval Hospital, Long Beach, Calif., and John F. Wetegrove, Raymondsville, Texas, to a residency in internal medicine, Naval Hospital, San Diego, Calif.

The following medical officers have been nominated to attend courses of postgraduate instruction: Comdr. Leo W. Olechowski of Detroit to a fellowship in surgery at Northwestern University (Cook County Hospital, Chicago); Lieut. Comdr. Louis P. Ballenberger of Hamlet, N. C., to a residency in otolaryngology at the Naval Hospital, Philadelphia; Lieut. Comdr. Henry R. Ennis of Rahway, N. J., to a fellowship in children's orthopedics at the North Carolina State Orthopedic Hospital, Gastonia, N. C., and Lieut. (jg) Robert A. Loeffler of Medford, Ore., to a residency in general surgery at the Naval Hospital, San Diego, Calif.

### PERSONALS

Comdr. James A. Fields, Retired, of South Boston, Va., and Capt. Richard B. Phillips, M.C.R., of Silver Springs, Md., have been voluntarily recalled to active duty.

Major Herbert G. Giddens, Capt. James P. Perrine and Capt. Robert K. Quinnel have been appointed for residency training in obstetrics and gynecology at the U. S. Naval Hospital, Portsmouth, Va.

## VETERANS ADMINISTRATION

### ELEVEN RADIOISOTOPE UNITS

With the new radioisotope unit at the Veterans Administration Hospital at Nashville, Tenn., the number of such units established by the Veterans Administration is eleven. The other units are at Veterans Administration hospitals in Los Angeles, San Francisco and Van Nuys, Calif.; Framingham, Mass.; New York; Cleveland; Chicago; Minneapolis; Dallas, Texas, and Fort Howard, Md.

In this new program, when a radioactive substance is administered along with remedial drugs, its distribution in the body is checked by means of photographic films or with some such electrical impulse equipment as the Geiger counter. The radioisotopes to be used at present are radiophosphorous, radioiodine, radioiron and radiosodium.

The radioisotope experts from Vanderbilt University in Nashville will work closely with the new radioisotope unit. Active work is expected to start at once. The program at Nashville will be under the general supervision of a special committee of which the hospital manager, Dr. W. E. Cooper, will be chairman and the chiefs of the hospital services will be members. The unit will be directed by Dr. George R. Meneely, assistant chief of medical services at the veterans hospital, who has already done outstanding research with radioisotopes. The Deans committee in Nashville will be represented in the project by a special committee composed of Drs. Howard Curtis, professor of physiology, chairman; Ernest Goodpasture, dean of the Medical School, and Francis G. Slack, professor of physics. Dr. Curtis will be consultant in biophysics to the unit, and Drs. Herbert Francis and Joseph Ivie consultants in radiology.

### RECENT APPOINTMENTS

The following recent transfers and appointments in the Department of Medicine and Surgery have been announced: Dr. John B. Floyd, manager of the Veterans Administration hospital in Outwood, Ky., formerly chief medical officer of the Veterans Administration office in Lexington, Ky.; Dr. Carleton Bates, manager of the Brooklyn, New York, Veterans Administration hospital, formerly with the Veterans Administration hospital in Castle Point, N. Y.; Mr. Noel M. Jaffrey, manager of the Castle Point hospital, formerly staff member of the Brooklyn Veterans Administration hospital; Dr. George S. Littell, manager of the Veterans Administration hospital in Amarillo, Texas, formerly chief of professional services of the Veterans Administration hospital in Temple, Texas.

A recent transfer includes: Dr. Joseph G. Spendlove, chief of professional services of Veterans Administration branch office no. 11 in Seattle, Wash., to the Veterans Administration center in Fort Harrison, Mont., as chief medical officer.

Other recent appointments include: Dr. Albert Oppenheimer as chief, radiological service, Providence, R. I., hospital, and Dr. Pierre E. Provost as chief of eye-ear-nose-throat service, Veterans Administration center, Togus, Maine.

## REVISED REGULATIONS FOR HOMES FOR PARALYZED VETERANS

The regulations governing the eligibility of paralyzed veterans for grants for use in acquiring homes especially designed for wheel chair living have been revised, the Veterans Administration announces, to eliminate the requirement that the veteran's bladder and bowel functions must be paralyzed in order to qualify for a grant up to $10,000. That requirement was in the original instructions issued by the Veterans Administration as contained in Public Law 702 of the 80th Congress. The language of the new instruction defines paralysis of the legs and lower part of the body as "paralysis of both lower extremities produced by lesion of the spinal cord resulting from disease or injury thereof, such as to preclude locomotion without the aid of braces, crutches, canes or a wheel chair, accompanied by paralysis of the lower trunk."

All applications previously disallowed under the original definition will be reviewed in the light of the new instructions. It has been estimated that more than 2,000 veterans may qualify for grants under this law. No veteran who has been turned down need reapply.

---

# PUBLIC HEALTH SERVICE

## INFLUENZA INFORMATION CENTER ESTABLISHED

Surgeon General Scheele of the Public Health Service announced December 24 that a plan has been developed by the Surgeons General of the Army, Navy, Air Force and Public Health Service to prevent a serious epidemic of influenza like that which occurred in 1918 and that an Influenza Information Center has been established at the National Institutes of Health, Bethesda, Md. The plan is part of an international program set up by the World Health Organization the objectives of which are to identify new strains of influenza virus as they appear and to evaluate their usefulness for incorporation in influenza vaccine. The program, the success of which will depend largely on the prompt reporting by local physicians and health officers of all suspected cases of influenza, will operate in the United States as follows:

When a significant outbreak of respiratory disease suspected to be influenza has been reported in a given community, the Influenza Information Center will alert diagnostic laboratories in the region, asking them to carry out serologic tests on patients for the presence of antibody against the influenza virus. Certain laboratories will also be asked to assign the affected community a team of investigators experienced in the technics of isolating the virus. As soon as these investigators isolate a new strain of virus, they will send it at once for a complete antigenic analysis to the Strain Study Center of the Influenza Commission, Army Epidemiological Board, Long College of Medicine, Brooklyn. Appropriate strains of the virus which have been isolated will be considered for possible inclusion in commercial vaccine.

While the cooperation of all diagnostic laboratories in the nation is being sought, a number of especially qualified laboratories has been formally invited to participate in the program, and fifty-six have already accepted this invitation.

The international influenza program was proposed during the Fourth International Congress for Microbiology at Copenhagen in July 1947. Two months later the Interim Commission established the International Influenza Center at the National Institute for Medical Research in London. The World Health Organization at its first World Health Assembly approved continuance of this center and recommended that all nations be invited to set up organizations to collaborate with it. The Surgeon General, U. S. Public Health Service, referred this proposal to Dr. R. E. Dyer, Director of the National Institutes of Health, who passed it on for advice to the Virus and Rickettsial Study Section at the Institutes. This group recommended that the program in the United States be built largely around the Army's Influenza Strain Study Center at Long Island College of Medicine and should use existing facilities for investigating influenza.

A committee comprising representatives of the four Surgeons General adopted these recommendations. It was further decided that an Influenza Information Center be established to administer the program in this country and to serve as liaison office between the International Influenza Center and participating American laboratories.

A list of these laboratories follows. The asterisk indicates those equipped for virus isolation as well as serologic tests:

LABORATORIES OPERATED BY THE FEDERAL GOVERNMENT

*Department of the Army*

Army Medical Dept. Research and Graduate School, Washington, D. C.
*First Army Area Medical Laboratory, 90 Church St., New York
Second Army Area Medical Laboratory, Ft. G. G. Meade, Md.
Third Army Area Medical Laboratory, Ft. McPherson, Ga.
*Fourth Army Area Medical Laboratory, Ft. Sam Houston, Texas
Fifth Army Area Medical Laboratory, Ft. Sheridan, Ill.
*Sixth Army Area Medical Laboratory, Ft. Baker, Calif.

*Department of the Navy*

*Navy Medical Research Unit No. 4, Great Lakes, Ill.

*Public Health Service*

*Laboratory of Infectious Diseases, National Institutes of Health, Bethesda, Md.
*Virus Laboratory Branch, Communicable Disease Center, Montgomery, Ala.
*Rocky Mountain Laboratory, Hamilton, Mont.

LABORATORIES OPERATED BY STATE AND LOCAL GOVERNMENTS

*State Laboratories*

*California, Dept. of Public Health, Berkeley
Florida, Board of Health, Jacksonville
*Illinois, Dept. of Public Health, Chicago
Indiana, State Board of Health, Indianapolis

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## ALABAMA

**Portrait of Dr. Harris.**—A portrait of Dr. Seale Harris, Birmingham, professor emeritus of medicine, was presented to the Medical College of Alabama on the evening of December 17 as a gift of the doctors of Alabama. Dr. Harris was professor of medicine at the Medical College of Alabama when the school was located in Mobile. He has also done renowned work on hyperinsulinism and as a medical biographer. The presentation was made by Dr. Lon Grove of Atlanta.

## COLORADO

**Governor's Health Council.**—A committee of thirty-three persons has been appointed by Governor Lee Knous to organize a legislative campaign for the passage of proposed health bills to be introduced in the 1949 state legislative session and to carry on a statewide educational program regarding the bills. Dr. Florence R. Sabin, Denver, is chairman.

**Grants to Medical Center.**—The University of Colorado Medical Center received more than $250,000 in the year ending November 1 for 131 major projects under way at the center. Grants in aid from private sources totaled $36,953, and the rest was received from government agencies. The totals do not include funds received from the Child Research Council. Eleven major government projects are sponsored by the U. S. Public Health Service and the Army and Navy.

## DISTRICT OF COLUMBIA

**Society Cites Christie and Wall.**—The Medical Society of the District of Columbia presented certificates for meritorious service to Drs. Arthur C. Christie and Joseph S. Wall at their recent annual meeting. Dr. Christie was cited as a "public-spirited citizen [who] has by his unflagging interest and wholehearted endeavor greatly advanced the cause of better medical care." Dr. Wall, who was head of the department of pediatrics at Georgetown University School of Medicine, was cited for his outstanding contribution as a citizen and credited with having done more than anyone else for passage of the present Healing Arts Practice Act in the District of Columbia. Both physicians are past presidents of the society.

**Cancer Research.**—Checks for two grants for cancer research were given to George Washington University by the District and American cancer societies. The funds will be used to provide facilities for all projects now being carried on at the Warwick Memorial Clinic. These facilities will include hiring a chemist for a radioactive tracer laboratory under the direction of Paul K. Smith, Ph.D., professor of pharmacology, the hiring of a tissue culture technician for the screening of chemicals as regards their action on malignant cells and the maintenance of four beds in George Washington University Hospital for cancer cases under study. This brings to eight the number of such beds now being maintained at the hospital. The other four are being supported as part of a cooperative venture between the university and the National Institutes of Health.

## ILLINOIS

**Conferences on Rural Health.**—The Illinois State Medical Society has arranged two conferences on health problems of rural areas during January. The session which meets at the Emmerson Hotel, Mount Vernon, January 20, will bring in farm, medical, 4-H Club and state health leaders by invitation from the counties of about one third of the state south of a line through Calhoun County. The Peoria conference covers the area to the north and west. Discussions on tuberculosis, the hospital construction act as it affects Illinois planning, the opportunities offered youth in medicine and allied professions and the compulsory health insurance programs are on the program; these and cancer and county health departments will be discussed at the second conference, to be held at the Pere Marquette Hotel, Peoria, January 21.

**Suburban Health Survey.**—The Committee on Chicago-Cook County Health Survey, Health Division of the Council of Social Agencies of Chicago-Cook County, says that suburban health service is short of help. There are 40 public health nurses in Cook County outside of Chicago to watch over its 800,000 population, a proportion of 1 to nearly 20,000; modern public health standards call for a proportion of 1 to 5,000. There should be, the committee says, nearly 160 nurses. The proposed 1949 budget asks for 12 additional. The deficiency is equally manifest in other phases of public health work. Public health standards call for 1 sanitary engineer and 1 sanitarian for every 50,000 population and 1 health educator and 1 nutritionist for every 100,000, or a staff of 16 engineers, 16 sanitarians, 8 educators and 8 nutritionists. Against that ideal standard, the department has 4 sanitary engineers and 1 each of the other categories. The survey committee is urging the board of commissioners of Cook County to provide a substantial increase for suburban public health work in 1949. The increase in suburban population, some 175,000 persons in five years, has intensified the needs of the Cook County Department of Public Health, which has asked a budget of $352,000, compared to $146,000 last year. With this increase, according to a spokesman of the survey, suburban expenditure for health protection will be far below the minimum standard of $1 per capita.

### Chicago

**Appoint Chairman of Pediatric Department.**—Dr. John A. Bigler has been named acting chairman of the department of pediatrics at Northwestern University Medical School and medical director of Childrens Memorial Hospital, replacing Dr. Stanley Gibson, who retired December 1. Dr. Bigler has been a member of the medical faculty since 1930 and associate professor of pediatrics since 1944. He is a graduate of Rush Medical College, 1923.

**Exhibit in Memory of Dr. Irving Cutter.**—To honor the late Dr. Irving S. Cutter, former health editor of the *Chicago Daily Tribune* and for many years dean of Northwestern University Medical School, the university recently opened an exhibit of photographs, manuscripts and rare volumes in its Chicago campus medical library. Dr. Cutter took over the *Tribune* "How to Keep Well" column after the retirement of its previous editor, the late Dr. William A. Evans, in 1934, and conducted it until his death Feb. 2, 1945. The exhibit includes rare books from Dr. Cutter's collection of early works on midwifery and manuscripts of his original contributions in the fields of medical education and history.

**Personals.**—Dr. Louis N. Katz, director, cardiovascular department, Michael Reese Hospital, was the guest speaker at the postgraduate course in cardiology given November 29 to December 2 by the Dallas (Texas) Southern Clinical Society. He also addressed the Dallas Internists Club on "The Control of the Coronary Circulation" and the Dallas County Medical Society on "The Progress of Coronary Disease."——Dr. Ludvig Hektoen was awarded the first Honorary Fellowship in the College of American Pathologists October 11 in acknowledgment of his distinguished career and outstanding service to pathologists.——Dr. James T. Case was presented the Merito Militar Medal recently in ceremonies in México, D. F. He was commended for his assistance to Mexican physicians who have come to the United States for postgraduate specialty training, some of whom served as his residents.

**Institute of Medicine.**—At the annual meeting of the Institute of Medicine of Chicago on December 7, an illuminated parchment scroll was presented to Dr. George H. Coleman by the board of governors and officers as a tribute of appreciation for his outstanding contribution to the welfare of the institute throughout twenty-five years of continuous service as secretary. Drs. Warren W. Furey, Eric Oldberg, Charles B. Puestow and H. Prather Saunders were elected to the board of directors. Officers for 1949 are Drs. Henry T. Ricketts, chairman of the board of governors; William F. Petersen, vice chairman of the board; Herman L. Kretschmer, president; Archibald L. Hoyne, vice president; George H. Coleman, secretary, and Grant H. Laing, treasurer.——Citizen fellowship in the Institute of Medicine was conferred on Miss Ella M. Salmonsen, medical librarian of the John Crerar Library, for her contributions as medical librarian, compiler and indexer.

## INDIANA

**State Medical Election.**—Dr. Augustus P. Hauss of New Albany assumed the presidency of the Indiana State Medical Association January 1, and Dr. Claude S. Black of Warren became president-elect. Dr. Arthur F. Weyerbacher of Indianapolis is treasurer.

**Sewage Treatment Plants.**—Eighty-nine Indiana cities and towns are planning sewage plants or additions to existing facilities to cost $47,000,000. Under the program 95 per cent of the state's urban population will be included in the areas where treatment is provided.

**Set Date for Centennial Meeting.**—The centennial celebration of the Indiana State Medical Association will be held September 26-29 at Indianapolis. Dr. J. Neill Garber of Indianapolis is chairman of the committee on arrangements. An extensive program will be developed.

## MARYLAND

**New Department of Biophysics.**—Five scientists have been named to faculty posts in a new Johns Hopkins University department of biophysics, now called the Jenkins Department of the university in honor of the late Thomas C. Jenkins. Dr. Haldan K. Hartline, professor of biophysics and chairman of the new department, is a graduate of Johns Hopkins University, a former fellow of the National Research Council in medical sciences and from 1936 to 1940 and from 1942 to the present was on the faculty of the University of Pennsylvania. Others named are John P. Hervey, M.S., Martin G. Larrabee, Ph.D., Frank Brink Jr., Ph.D., and Philip W. Davies. Dr. Larrabee and Mr. Davies are associate professors, and Dr. Brink and Mr. Hervey assistant professors. All of the new appointees are at the University of Pennsylvania, where they have been working with Dr. Bronk in biophysics. Dr. Bronk became president of Johns Hopkins University January 1.

## MISSOURI

**Honor Bulletin Editor.**—The Council of the Greene County Medical Society recently honored Dr. Paul F. Cole, Springfield, founder of the society's *Bulletin*, past president and for twenty-seven years an active member, by elevation to honor membership. Dr. Cole founded the *Bulletin* in 1942 to keep members at home and at war informed of local activities. He relinquished the editorship in 1947 but served in an advisory capacity until his retirement last June.

## NEW JERSEY

**Dr. Winnek Dies.**—Philip S. Winnek, Ph.D., who when research chemist for the American Cyanamid Company in Stamford, Conn., played a part in the development of sulfadiazine and sulfaguanidine, died in the Morristown Memorial Hospital December 18, aged 40.

**Meeting on Tumors.**—The New Jersey Oncological Society will hold a panel discussion January 11 at 9 p. m. at St. Michael's Hospital, Newark. Subjects under discussion will be "The Biologic Aspects of Neoplasms," "The Effect of Nutrition on Rous Chicken Sarcoma," and "Comparison of Rous Chicken Sarcoma to Human Neoplasia." Membership is open to doctors of New Jersey interested in the study of tumors and in good standing in their local county medical society.

## NEW YORK

**Society News.**—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged the following lecture for the Jefferson County Medical Society January 13, 8:30 p. m. at the Hotel Woodruff in Watertown. Dr. Albert J. Ritzmann, New York, will speak on "Disorders of the Thyroid Gland: Diagnosis and Management; Use of Thiouracil."

**Increase State Aid to Crippled Children.**—Beginning January 1 state aid to general and convalescent hospitals for rehabilitation of physically handicapped children was increased from $750,000 to $900,000 a year. The maximum daily rate for care of children in general hospitals was increased from $6.25 to $8.50, with the state paying half. New York City will pay the other half for its residents, and upstate the county will pay it. Maximum daily rate for care of children in convalescent hospitals is increased from $5 to $6 a day. During 1947 the number of physically handicapped children including spastics, paralytics and amputees cared for in hospitals with state aid was 5,600. Most of those assisted are under 21 years of age, but a small number of persons over that age who have suffered from poliomyelitis are eligible for treatment.

### New York City

**Fourth Harvey Lecture.**—Dr. Carl F. Schmidt, professor of pharmacology, University of Pennsylvania School of Medicine, Philadelphia, will deliver the fourth Harvey Lecture of the current series at the New York Academy of Medicine on January 20, on "Quantitative Measurement of Cerebral Blood Flow in Man."

**New York University Doctors Receive Army-Navy Award.**—The Certificate of Appreciation, a joint U. S. Army-Navy award for "patriotic civilian service," was recently presented to three New York University College of Medicine faculty members: Dr. William S. Tillett, chairman of the department of medicine; Dr. Colin M. MacLeod, chairman of the department of microbiology, and R. Keith Cannan, D.Sc., chairman of the department of chemistry.

**Salmon Memorial Lectures.**—Dr. Stanley Cobb, Bullard professor of neuropathology at Harvard Medical School since 1926, has been selected the Salmon Memorial Lecturer for 1949. Dr. Cobb has been psychiatrist in chief of the Massachusetts General Hospital for the last fifteen years. The Salmon Committee on Psychiatry and Mental Hygiene, appointed by the New York Academy of Medicine, has selected as the lecturer each year since 1932 a specialist who has made some outstanding contribution.

**Panel Discussions for General Practitioners.**—Five panel discussions in medicine and surgery to aid the general practitioner will be held at the New York University-Bellevue Medical Center beginning January 26 and extending through May 25. Questions from the floor will play a prominent part in each session. Sponsored by the Alumni Association, New York University College of Medicine, the panels will make available to doctors of the Greater New York Area, without cost, the experience of more than twenty faculty members of the College of Medicine, Cornell Medical School and the Columbia University College of Physicians and Surgeons. All sessions will be held from 8:30 to 10 p. m. Admission will be by card, and arrangements are under the direction of Dr. William Goldring, chairman, Committee on Science and Education, Alumni Association, New York University College of Medicine. The schedule is as follows:

Jan. 26, Arthritis. Moderator, Currier McEwen; Richard H. Freyberg, Edward F. Hartung and Otto Steinbrocker.
March 2, Hypertension. Moderator, Herbert Chasis; George A. Perera, William Goldring, J. William Hinton and Homer W. Smith.
March 30, Peripheral Vascular Diseases. Moderator, Ludwig W. Eichna; Wallace B. Murphy, Emanuel M. Papper, and Julius J. Sachs.
April 27, Congenital Heart Disease. Moderator, Clarence E. de la Chapelle, with Janet S. Baldwin, Charles S. Kossmann, Herbert C. Maier and Henry K. Taylor.
May 25, Antibiotics. Moderator, Colin M. MacLeod.

**Seminar on Venereal Disease.**—A panel of specialists in the diagnosis and treatment of syphilis and gonorrhea will conduct a seminar on venereal disease at the New York City Department of Health, which begins January 15, and will continue weekly thereafter through April 30. Meetings will be held at 10:30 a. m. in the second floor auditorium of the health department, 125 Worth Street, Manhattan. Attendance will be open to physicians, nurses, social workers, laboratory personnel, teachers and others concerned with the control of venereal disease. The lecture schedule follows:

Jan. 15, Evan W. Thomas, Modern Treatment of Early Syphilis.
Jan. 22, Adolph Jacoby, Treatment of Gonorrhea.
Jan. 29, Borris A. Kornblith, Treatment of the Minor Venereal Diseases.
Feb. 5, Richard C. Arnold, Serodiagnosis of Syphilis.
Feb. 12, Holiday.
Feb. 19, Alfred Cohn, Diagnostic and Immunologic Aspects in the Field of Venereal Disease.
Feb. 26, Joseph E. Moore, Office Management of the Patient with Syphilis.
March 5, Samuel S. Paley, Cardiovascular Syphilis.
March 12, Norman R. Ingraham Jr., Philadelphia, Syphilis in Pregnancy.
March 19, Bernard I. Kaplan, Latent and Late Syphilis.
March 26, E. Gurney Clark, The Physician as an Epidemiologist in Venereal Disease.
April 2, Frank C. Combes, Differential Diagnosis of Early Syphilis.
April 9, Dabney Moon-Adams, Congenital Syphilis.
April 16, William Leifer, Ambulatory Treatment of Syphilis.
April 23, Bernhard Dattner, Syphilis of the Central Nervous System.
April 30, Milton Helpern, Syphilis and Sudden Death.

## PENNSYLVANIA

**The Donora Disaster.**—Dr. Clarence A. Mills, head of the Experimental Medicine Department at the University of Cincinnati College of Medicine, on returning from his third visit to investigate the recent Donora situation stated that the Borough Council at his suggestion has undertaken a house to house survey in that community which at the time of his preliminary report had included 7,670 of the town's 13,500 citizens. The situation at Donora on October 30 is suspected of being caused by fumes from a zinc smelter. Dr. Mills said that more than 5,000 of the inhabitants are being found affected by the October 30 poisoning smog in addition to the 20 human deaths and some 800 animals killed.

### Philadelphia

**Grants for Psychiatric Training.**—The Woman's Medical College has received $37,302 as a grant under the National Mental Health Act for developing psychiatric training for undergraduate medical students. The funds will be made avialable for the school year 1949-1950 and will be paid in annual allotments over a three year period.

## TENNESSEE

**Oak Ridge Institute of Nuclear Studies.**—Dr. Marshall H. Brucer, assistant professor of physiology at the University of Texas School of Medicine, Houston, has been appointed chairman of the Medical Division of the Oak Ridge Institute of Nuclear Studies to direct the cancer research program and the training of medical and research personnel. Russel S. Poor, Ph.D., dean of the Graduate School of Alabama Polytechnic Institute, Auburn, was also recently named chairman of the University of Tennessee Relations Division of the institute. Both men assumed duties January 1. The institute program, which will be housed in a section of the Oak Ridge Hospital, will have facilities for treating a limited number of patients who will be drawn from twenty Southern medical schools which are participating in the program. Patients will be admitted only through special committees set up at the cooperating medical schools. It will be some months before patients can be accepted. Dr. Brucer is a graduate of Northwestern University Medical School, Chicago, 1942. He served as surgeon in the Airborne Command at Camp Mackall, N. C., for two and a half years during the late war, after which he was on the medical staff of Bruns General Hospital (U. S. Army) in Santa Fe, New Mexico. He joined the University of Texas Medical School after his release from the Army in 1946.

## VIRGINIA

**The Stoneburner Lecture.**—Dr. Eugene A. Stead Jr., professor of medicine, Duke University School of Medicine, Durham, N. C., will deliver the Lewis T. Stoneburner III Lecture at the Medical College of Virginia, Richmond, January 14. This lectureship was established at the college last year by friends who were members of the 45th General Hospital with Capt. Stoneburner, an honor graduate in medicine at the college in the class of 1937, who lost his life in World War II.

## WISCONSIN

**Convocation Speaker.**—Dr. Oscar G. Moland, Augusta, will speak at the convocation of the University of Wisconsin Medical School, Madison, January 12 at 4 p. m. in the Service Memorial Institutes Building. His subject will be "From the Viewpoint of the Country Physician." Dr. Moland is a graduate of the university, 1935.

**Broadcast Postgraduate Programs.**—The University of Wisconsin Medical School, Madison, will use the frequency modulation facilities of the university's radio station WHA in presenting from time to time conferences, symposiums and medical lectures focused primarily for the medical practitioner of Wisconsin. Arrangements for programs and provision for local frequency modulation reception will be made with county medical societies. This is believed to be the first time that scientific medical material has been broadcast by a medical school through a state owned university radio station. The first program concerning the human back will probably be given in February.

## GENERAL

**Board of Ophthalmology.**—The American Board of Ophthalmology wishes to make known that it does not evaluate, approve or disapprove any ophthalmic residency as fulfilling the requirements for candidates for board examinations. Any candidate who qualifies for the board examination and completes the prerequisites as outlined in the syllabus will be accepted. A copy of the syllabus can be obtained from the secretary of the American Board of Ophthalmology, 56 Ivie Road, Cape Cottage, Maine.

**Southeastern Allergy Meeting.**—The annual meeting of the Southeastern Allergy Association will be held at the Washington-Duke Hotel, Durham, N. C., January 22-23. Dr. George E. Rockwell, Milford, Ohio, president of the American College of Allergists, and Dr. Walter Winkenwerder, Baltimore, president of the American Academy of Allergy, are to be guest speakers. A panel on "Infectious Asthmas," headed by Dr. Oscar Swineford Jr., Charlottesville, Va., and a panel on "Food Allergies," headed by Dr. Hal M. Davison, Atlanta, Ga., are on the program. For information address Dr. Katharine B. MacInnis, Secretary, 1515 Bull Street, Columbia, S. C.

**Posing as a Doctor.**—A man using the name of Paul Lambert is [illegible] posing as a doctor, according to the Bureau of [illegible] He is about 31 years old, 5 feet 9½ inches (176.5 cm.) tall, weighs 125 to 130 pounds (56.7 to 59 Kg.), has dark brown hair parted on left side, wears steel-rimmed glasses, has a cast in one eye and a small dark mustache. He has succeeded in obtaining sums of money to be invested in a South American business venture. He claims to be a resident or a native of Brazil and an undercover liaison officer between the United States and Brazil. Anyone knowing the whereabouts of this imposter should notify the Bureau of Police, Philadelphia 7.

**Conference on Medical Service.**—The National Conference on Medical Service will be held at the Palmer House, Chicago, February 6. The program is as follows:

Chris J. D. Zarafonetis, Ann Arbor, Mich., and George E. Wakerlin, Chicago, Legalized Medical Research.
Frank Calderone, New York, Progress of the World Health Organization.
Creighton Barker, New Haven, Conn., Progress of the World Medical Association.
Warren F. Draper, Washington, D. C., Medical Program of the United Mine Workers of America Welfare and Retirement Fund.
Mr. James D. Boyle, What's Happening in Washington This Week, followed by a discussion to be opened by Joseph S. Lawrence.
George N. Aagaard, Minneapolis, Minn., Charles W. Smith, Harrisburg, Pa., and Harold I. Goldman, Denver, Panel discussion: Postgraduate Education of the Doctor.
Wilbur Bailey, Los Angeles, Can Corporations Such as Hospitals Legally Engage in the Practice of Medicine?

The luncheon speaker will be Dr. George F. Lull, Secretary and General Manager, American Medical Association, Chicago.

**Annual Meeting of Society for Surgery of the Hand.**—The American Society for Surgery of the Hand will meet at Thorne Hall, Northwestern University, Chicago, January 21-22. Those speaking by invitation are Drs. Joseph L. Posch, Detroit, "Primary Nerve and Tendon Repair" and Frederick L. Liebolt, New York, "Arthroplasty for Ankylosis of the Metacarpophalangeal Joint." Other speakers will be:

Vinton E. Siler, Cincinnati, Tenorrhaphy.
R. Sterling Mueller, New York, Treatment of Severed Flexor Tendons in the Flexor Tendon Sheaths of the Fingers.
J. Edward Flynn, Boston, Acute Suppurative Tenosynovitis of the Hand.
George S. Phalen, Cleveland, Median Nerve Neuritis.
Lt. Col. Gilbert L. Hyroop, Phoenixville, Pa., Plastic Repair of the Cleft between the Thumb and Index Finger.
Lot D. Howard Jr., San Francisco, Thumb Web Contracture.
J. William Littler, New York, Adduction Contracture of the Thumb.
Julian M. Bruner, Des Moines, Ia., Dupuytren's Contracture.
William Metcalf, Hines, Ill., Skeletal Reconstruction in the Hand.
W. Brandon Macomber, Albany, N. Y., Relationship of Superficial and Deep Reconstructive Surgery of the Hand.
Thomas W. Stevenson, New York, Xanthoma of the Hands.
Sumner L. Koch, Michael L. Mason and Harvey S. Allen, Chicago, Presentation of Cases.

## PUERTO RICO

**Discuss Need for Medical School.**—For the first time in Puerto Rico, the need of a medical school for the island was discussed by experts in a round table at the School of Tropical Medicine in San Juan, December 6. At the annual convention of the Puerto Rico Medical Association five doctors and the chancellor of the University of Rio Piedras met with doctors from the United States, Cuba and the Dominican Republic. Dr. Herman Weiskotten, dean of the University of Syracuse Medical School, said that the minimum cost of a small school would be from $400,000 to $500,000 a year, to say nothing of the additional expense for the school hospital. Other speakers were Commissioner of Health Juan A. Pons, who favored early establishment of the school; Dr. Oscar Costa Mandry, who four years ago made for the university a survey of American institutions in connection with the possibility of establishing a medical school in Puerto Rico; Dr. Guillermo Arbona and Dr. Enrique Koppisch, who was also the participant to come out definitely against the school. Chancellor Jaime Benitez declared that the conditions described by Dr. Koppisch made the need for a medical school "only more pressing."

# Marriages

William Francis Maguire, Charleston, S. C., to Miss Dorothy Eileen Bennett, of Holly Hill, October 30.

Earle Sinclair McKey Jr., Valdosta, Ga., to Miss Martha Augusta Wiseman of Adel, October 23.

Joseph Cooper Collins to Miss Marjory Joan Hubbard, both of San Francisco, September 18.

Charles Harrison Wiygul to Miss Frances Allen Varner, both of Fairfield, Ala., October 30.

Max L. Salvater to Miss Laura Kraemer, both of Sacramento, Calif., October 9.

Kathleen Byers to Mr. William John Lindsey, both of Atlanta, September 10.

# Deaths

**William Augustus Evans,** Aberdeen, Miss., formerly health commissioner of Chicago, died on a plantation near Muldon, Miss., November 8, aged 83, of heart disease. Dr. Evans was born in Marion, Ala., Aug. 5, 1865. He received his medical degree from the Medical Department of Tulane University of Louisiana, New Orleans, in 1885, and later moved to Chicago, where from 1891 to 1895 he was demonstrator of pathology and from 1895 to 1908 professor at the College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois. In 1908 he joined the faculty of Northwestern University Medical School in Chicago, where at the time of his death he held the title of professor of public health emeritus. He was a member of the American Medical Association and in 1902 and in 1912 a member of the House of Delegates, a president of the Chicago Medical Society in 1902-1903, and of the American Public Health Association in 1916-1917. In 1907 he became health commissioner of Chicago, serving until 1911, when he resigned to become health editor of the *Chicago Daily Tribune*, where for twenty-three years he conducted the column on "How to Keep Well." He was a member of the board of medical advisors of the Illinois Department of Health, a member of the advisory committee of the Chicago Health Department and on the staffs of the Wesley Memorial, Cook County and Alexian Brothers hospitals in Chicago. He received LL.D. degrees from Tulane University in 1910 and the University of Mississippi in 1921 and a doctor of public health degree from the University of Michigan, Ann Arbor, in 1911. Dr. Evans presented his home town of Aberdeen with a library of some 15,000 volumes and 10,000 manuscripts as a memorial to the Evans family, which for generations lived in that section of the state. He also restored the old home of Jefferson Davis, "Beauvoir," in Biloxi, Miss., converting it into a public building now maintained by a Davis memorial association.

**William Stoutenborough Terriberry** ⊕ Medical Director, U. S. Public Health Service, retired, Old Lyme, Conn.; born in Paterson, N. J., July 3, 1871; Columbia University College of Physicians and Surgeons, New York, 1896; veteran of the Spanish-American War; a lieutenant colonel in the medical corps of the New York National Guard; served in the Mexican border campaign of 1916; served during World War I; entered the public health service as a senior surgeon in the reserve corps in 1919 and later was made assistant surgeon general; his assignments included acting as supervising officer for immigration along the Canadian border; commissioned medical director in the regular corps in 1930, served as director of Public Health Service District number 1, New York, and as medical officer in charge, U. S. Marine Hospital, Buffalo; retired from the service in 1937; received the Conspicuous Service Cross in 1922; at one time on the staff of the Bellevue Hospital in New York; died in the U. S. Coast Guard Academy Hospital, New London, October 13, aged 77, of arteriosclerotic heart disease.

**Voyle Musser James** ⊕ Los Angeles; born in Salt Lake City, Jan. 30, 1899; University and Bellevue Hospital Medical College, New York, 1924; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology, American College of Allergists and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; past president of the Hollywood Academy of Medicine; affiliated with the Children's, Cedars of Lebanon and the Presbyterian Hospital-Olmsted Memorial in Los Angeles and the Glendale (Calif.) Sanitarium and Hospital; died October 17, aged 49, of coronary disease.

**Charles Edward Futch** ⊕ Los Angeles; born in Cleveland, Jan. 23, 1898; University of Michigan Medical School, Ann Arbor, 1923; assistant professor of otolaryngology at the College of Medical Evangelists; specialist certified by the American Board of Otolaryngology; member of the Pacific Coast Oto-Ophthalmological Society and the Los Angeles Society of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons and the International College of Surgeons; served during World Wars I and II; on the staffs of St. Vincent's, Queen of Angels and White Memorial hospitals; died October 24, aged 50.

**Charles Vernon Crane** ⊕ Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and member of the American Heart Association, American Diabetes Association and National Gastroenterological Association; served during World War I; affiliated with Blodgett Memorial, St. Mary's and Butterworth hospitals; died October 10, aged 66, of coronary thrombosis.

**William Frederick Doolittle,** Cleveland; Western Reserve University Medical Department, Cleveland, 1898; died in Lakeside Hospital October 23, aged 76, of brain abscess.

**Eli Hamlin Dunn,** Kansas City, Mo.; Rush Medical College, Chicago, 1885; died September 30, aged 90, of senility.

**Walfred August Engstrom,** Huntington Park, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1944; member of the American Medical Association; certified by the National Board of Medical Examiners; interned at the Los Angeles County Hospital; affiliated with the Mission Hospital, Huntington Park, St. Francis Hospital, Lynwood and the Bell Mission Hospital in Bell; died in Los Angeles October 22, aged 40, of injuries received when struck by an automobile.

**Albert Wilford Goodale,** Orland, Ind.; University of Buffalo School of Medicine, 1907; died in Los Angeles September 10, aged 75.

**Harvey H. Hartley,** Goldendale, Wash.; University of Oregon Medical School, Portland, 1900; served as county health officer, postmaster and president of the chamber of commerce; drowned September 10, aged 77.

**John William Ottoway Henley,** Kansas City, Mo.; Meharry Medical College, Nashville, Tenn., 1919; died in San Diego, Calif., recently, aged 52, of cerebral thrombosis.

**Carl F. W. Lippe,** Newark, N. J.; University of Georgia Medical Department, Augusta, 1897; died recently, aged 78, of uremia and arteriosclerosis.

**Leon Dudley Long** ⊕ Seattle; the Hahnemann Medical College and Hospital, Chicago, 1907; affiliated with the Virginia Mason Hospital, where he died recently, aged 66, of myocardial infarction.

**William E. Morris,** Shelbyville, Ky.; Bellevue Hospital Medical College, New York, 1890; member of the American Medical Association; died in King's Daughters' Hospital September 27, aged 84, of carcinoma of the prostate.

**Adolph Jacob Osterman,** Mount Vernon, Wash.; Gross Medical College, Denver, 1896; member of the American Medical Association; served during World War I; died recently, aged 80, of metastatic carcinoma of the lungs.

**Rudolph Emanuel Pick** ⊕ New York; University and Bellevue Hospital Medical College, New York, 1903; consultant on the staffs of the Metropolitan and Flower and Fifth Avenue hospitals; died in the Nathan Littauer Hospital, Gloversville, September 21, aged 66, of fracture of the femur.

**John Irving Pinckney,** Providence, R. I.; University of Vermont College of Medicine, Burlington, 1906; member of the American Medical Association; for many years executive secretary of the Providence Tuberculosis League; formerly affiliated with the Michigan State Board of Health; at various times on the staffs of the Western Maine Sanatorium in Hebron, Westfield (Mass.) State Hospital and the Rhode Island Hospital; died in the Jane Brown Memorial Hospital, October 16, aged 69, of coronary thrombosis.

**Julius Thomas Pitts,** Newborn, Ga.; Atlanta Medical College, 1895; member of the American Medical Association; retired minister; died September 21, aged 76.

**Ernest Rose,** San Marcos, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1936; member of the American Medical Association; served during World War II; died recently in Brooke General Hospital, Fort Sam Houston, aged 49, following an operation for brain tumor.

**William Frederic Singer** ⊕ Pueblo, Colo.; Syracuse University College of Medicine, 1896; on the staffs of Parkview and St. Mary's hospitals; died October 25, aged 78.

**James C. Spell,** Titusville, Fla.; University of Louisville (Ky.) Medical Department, 1906; also a pharmacist; died in the Eugene Wuesthoff Memorial Hospital, Rockledge, September 16, aged 73, of heart disease.

**Lynn D. Stewart** ⊕ Payson, Utah; Northwestern University Medical School, Chicago, 1911; at one time mayor; served during World War I; on the staff of Payson City Hospital; died September 22, aged 61, of coronary thrombosis.

**Benjamin Mortimore Stout** ⊕ Morgantown, W. Va.; Jefferson Medical College of Philadelphia, 1921; past president of the Monongalia County Medical Society; on the staff of Monongalia General Hospital; died September 27, aged 56, of coronary occlusion.

**Ernest Clifford White,** Chicago; Dunham Medical College, Chicago, 1902; served during World War I; medical director of Alexian Brothers Hospital, where he died October 14, aged 69, of coronary thrombosis.

### The Working of the National Health Service

The working of the National Health Service brings to light many drawbacks which might have been expected when the practice of medicine became state controlled, i. e., socialized. The glittering promises of large incomes is found to depend on a doctor's having a large list, up to 4,000 possible patients. In times of stress he is overworked and cannot properly investigate his serious cases. Much of his time is taken up with the clerical work of signing certificates and the other innumerable forms which bureaucracy has inflicted on him. Doctors practicing in sparsely populated areas or in rich suburban areas have suffered large losses of income. The number of inhabitants can give them only a limited list of National Health patients, whose capitation fees are only a small fraction of the sums previously paid for private attendance. In some cases the loss of income is stated to be as much as 50 per cent. No matter how much illness a well to do patient has in the year it is covered by the capitation fee of about $3.50.

Such abuses of the service as the following occur. Three doctors have written to the *British Medical Journal* stating that patients who on arrival found a queue in front of them at the office were unwilling to wait, returned home and telephoned for a visit. In another case a patient telephoned that he had a high temperature in order to obtain a visit, although his temperature was normal. In still another case a woman sent a message after 1 p. m. for a visit. But she was so well that three visits had to be paid to her house before she was found at home.

The proposal has been made that the maximum of 4,000 patients on a doctor's list should be reduced to 2,500 and the capitation fee increased to $8. Already the cost of dental treatment has proved to be more than double the estimate. The Minister of Health stated that he wanted to take money out of the doctor-patient relation. That is evidently going to be an expensive matter for the taxpayer. Similarly his colleagues state that they want to take the profit motive out of production. In the industries taken over by the state they certainly have accomplished this. No profits, but losses—at the expense of the taxpayer—have been made. Similarly "taking money out of the doctor-patient relation" is going to be an expensive matter for the state—much more expensive than was calculated. The medical profession does not reap a corresponding benefit, because of the enormous waste involved, waste of time and material, as shown in a previous letter. A crowning bit of extravagance may be mentioned. Foreigners who come to this country are to be entitled to free medical attendance at the public expense for the first two months.

### Organized Opposition: Lord Horder's Criticisms

The opposition of a section of the British Medical Association, led by Lord Horder, to acceptance of the Health Service has been reported in previous letters to The Journal. A new organization, called the Fellowship for Freedom in Medicine, was formed at a meeting in London which was attended by 673 doctors from all parts of the country. Lord Horder was elected chairman. In his opening speech he outlined the collapse of the British Medical Association's resistance to the Act. "We are no longer experts," he said. "We sit and sign forms. With no time to diagnose diseases we pass out patients to other persons and to institutions, knowing full well that they cannot dispense the health benefits which may or may not be needed." He suggested that a guild be formed. The old city guilds stood for a high standard in regard to the craft they pursued and took powers to preserve it in the public interest as well as in their own.

The meeting passed three resolutions covering its aims. The first dealing with its relations to existing bodies pointed out that it was in no way opposed to other organizations. The second affirmed its determination to maintain the highest possible standards of medicine in the future. The third was to the effect that the committee should consider ways and means in which freedom in medical matters could be preserved in the profession. Ten members of an executive committee were elected. Another ten will be chosen with the object of having a wide representation over the country as possible. So far, 1,750 letters have been received from members of the profession dissatisfied with the national health scheme, though no general appeal to the profession has been made. Letters are coming in at the rate of 30 a day.

### Protest Against Soviet Tyranny Over Science

Sir Henry Dale, F.R.S., the eminent pharmacologist, has resigned his honorary membership in the Academy of Sciences of the U.S.S.R. In his letter to the President he points out that in 1942, the year in which he was elected to the Academy, the Royal Society of London elected Nicholas Vavilov to be one of its fifty foreign members. As first director of the Lenin Academy of Genetics, Vavilov was reputed to be of great assistance to agriculture in the Soviet Union. But for some unknown reason, possibly political, he fell out of favor with those who followed Lenin. Not till 1945 did the Royal Society discover that he had been dismissed and had disappeared with a number of co-workers in genetics at some unknown date between 1941 and 1943. Repeated inquiries addressed to the Russian Academy by the Royal Society asking only the date and place of his death received no reply. It is now clear what happened. Vavilov has been replaced by T. D. Lysenko, the advocate of a doctrine of evolution which, in effect, denies all progress since Lamarck's speculations appeared early in the nineteenth century. This is not the result of an honest and open conflict of scientific opinions. Lysenko's own statements show that his dogma has been established and enforced by the Central Committee of the Communist Party as conforming to the political philosophy of Marx and Lenin. Decrees of the Academy show only too clearly the political tyranny which exists. The distinguished neurophysiologist L. Orbeli, of the school of the great Pavlov, was dismissed from the secretaryship of the Department of Biological Sciences because he had failed to anticipate the decrees restricting all teaching in genetics to the politically imposed orthodoxy. Since Galileo many attempts have been made to suppress scientific truth. None have been a success; the last was Hitler's. Dale concludes that he cannot continue an association which might appear to condone such tyranny.

### Dr. J. H. Sequeira

Dr. James H. Sequeira, a leading dermatologist, died in Kenya at the age of 83 years. After qualifying he decided to become a dermatologist and visited Vienna and Copenhagen for postgraduate study. In the latter capital he worked under Finsen, who was engaged in his pioneer researches on light baths in the treatment of cutaneous tuberculosis. In 1901 Sequeira translated Finsen's book on phototherapy and returned to the London Hospital, his medical school, to carry out the new methods in the recently established light department, the first in this country. In the same year he was the first in this country to report on the treatment of cancer of the skin by roentgen rays and radium. He published his treatise on "Diseases of the Skin" in 1911. It reached a fourth edition in 1927 and was translated into Spanish in 1926. A prolific writer, he for many years edited the *British Journal of Dermatology & Syphilis*.

On retiring from the active staff of the London Hospital in 1927 he went to Kenya, where he was president of the Kenya Branch of the British Medical Association and editor of the *East African Medical Journal*. His African experiences were embodied in his Chadwick lecture in 1932, on "The Educational Aspects of Public Health in the Tropics." During the first great war he was consultant in dermatology to the military hospitals of London. He was president of the Dermatological Section of the Royal Society of Medicine (1925 to 1927) and corresponding member of the French and Danish dermatological societies.

## GREECE

*(From a Special Correspondent)*

Athens, Dec. 2, 1948.

### Public Health Program in Greece

The Economic Cooperation Administration, recognizing the necessity of improving standards of public health and medical care as essential to economic recovery, has embarked on a huge hospital, health center and sanitation program and plans a reorganization of the health services of Greece. Funds have also been made available for sending selected Greeks to the United States for training and to send specialists to Greece from the United States and other countries participating in the Economic Cooperation Administration.

The Public Health Division of the Economic Cooperation Administration Mission, under the direction of Dr. O. F. Hedley of Richmond, Va., a medical director of the U. S. Public Health Service, is composed for the most part of commissioned officers of the service or specialists recruited by the service for the Economic Cooperation Administration. The Public Health Division consists of five medical officers, three sanitary engineers, three public health nurses, one hospital administrator, one hospital architect, two medical supply experts and one civil engineer. Altogether the division includes nineteen Americans, one British supply expert and twenty-four Greeks, several of whom are in professional or subprofessional categories.

The medical officers in addition to Dr. Hedley are Senior Surgeon Leslie W. Knott of San Francisco; Senior Surgeon (R) Paul A. Lindquist of Kansas City, Kan.; Surgeon (R) Paul F. Holland of Alexandria, Va., and Surgeon (R) Fred W. Love of Delray Beach, Fla., all of whom are assigned to the Greek Mission by the Public Health Service.

### Construction of Hospital and Health Facilities

Approval has been granted by the Economic Cooperation Administration in Paris and Washington and by the Government of Greece for the construction of hospital and health facilities during the current fiscal year in the amount of $10,234,000 in foreign exchange and drachmae equivalents and the importation of $1,450,000 worth of sanitation supplies and equipment. Over $70,000 has been earmarked for training purposes. In addition, the Economic Cooperation Administration has allocated $2,000,000 in local currency to meet the local construction costs of the hospital and health center program of the Greek War Relief, which amounts to over $10,000,000. The Public Health Division also has supervision over the importation of $2,950,000 worth of medical and sanitation supplies for the Greek Ministry of Hygiene and furnishes technical assistance in the importation of $6,000,000 worth of commodities for the trade. An amount of $300,000 has been made available for medical and sanitation supplies for refugee relief.

### Nursing School

Project agreements in the amount of $7,400,000 have been signed and construction has been started on a dormitory for the Athens Red Cross School of Nursing and two medical and sanitation supply warehouses. The current year's program includes the construction of a school of nursing in Salonica, a dormitory for nurses in Athens, two medical and sanitation supply warehouses, the completion of the Athens Maternity Hospital started before the war and a dormitory for midwives, repairs and equipment for the School of Hygiene and a modest amount for the University of Athens and Salonica medical schools, the completion of six general hospitals and the completion of four public health centers. Most of the buildings which will be completed were begun or projected before the war. In addition a number of buildings will be repaired or completed from the special drachmae accounts of the mission or funds in the Greek budget; these will require no dollar expenditures.

### Safe Water Supplies

The sanitation program, which amounts to $1,450,000, will consist primarily in furnishing safe water supplies to a number of small communities. Water and sewerage facilities for the larger towns are included in the public works program. The success of this program depends largely on obtaining pipe, which seems to be universally in short supply.

One of the greatest needs in Greece is for more trained nurses. On the basis of the latest figures of the Ministry of Hygiene, there are now 542 graduate nurses practicing their profession in Greece. This is approximately a ratio of 1 nurse to 14,000 population, as compared with 1 to 500 in the United States and United Kingdom. The objective of the mission, with the cooperation of the Greek War Relief Association, is to provide 300 graduates annually. Since this cannot be attained immediately several one year schools will be provided, and an inservice training program for the practical nurses now on duty has been begun. New technical motion pictures from the United States play an important role in the nurse-training program and are an integral part of the program.

### Medical Education

The Medical Schools of the Universities of Athens and Salonica have suffered extreme deterioration because of the war. Many of these buildings have been requisitioned for military hospitals. Furthermore, the number of students has increased beyond all possible needs of the country. Under the four year plan it is hoped to refurbish the building and reequip the laboratories and clinics, at least partially, and to reduce the "academic inflation." The School of Hygiene, established by the Rockefeller Foundation for the training of health officers, will also be repaired and furnished substantial equipment.

### Tuberculosis

Tuberculosis is the outstanding health problem affecting Greece at the present time. The mortality from tuberculosis is approximately 250 per 100,000 population, and there are less than 5,000 sanatorium beds. Bone and joint tuberculosis is especially common. The mission is assisting the International Childrens' Emergency Fund and the Scandinavian Red Cross Affiliates in a BCG program which should bring ten teams to Greece in early 1949. Under the four year plan it is hoped to provide about 9,000 additional sanatorium beds.

## PENICILLIN THERAPY

*To the Editor:*—The article "Acute Exfoliative Dermatitis and Death Following Penicillin Therapy," by Drs. J. Rabinovitch and M. C. Snitkoff (THE JOURNAL, October 16, pp. 496-498) implicated penicillin as the cause of death in the case reported, despite failure to perform an autopsy. A white woman aged 72 was operated on for a "gangrenous and perforated appendix." The peritoneal cavity was found to contain "free turbid fluid" which yielded a nonhemolytic streptococcus. Penicillin was administered for eleven days. Eighteen days after penicillin was begun, pruritus was noted, then a maculopapular rash, followed by fever. She was given several drugs, but the course was progressively downhill. The skin began to exfoliate, large bullae were formed, ulcerations of the mouth developed and acute conjunctivitis was noted. Death followed thirteen days after the first appearance of the eruption.

I should like to report a case similar in many respects. Until a necropsy, this was considered to be a drug eruption with penicillin in the list of offenders. The autopsy, however, revealed an extensive retroappendical abscess. This patient was seen at the University Hospital in Minneapolis in May 1947. A white man, aged 44, had a history of constant pain in the right side of the chest, of five weeks' duration. Three weeks prior to admission he had received penicillin, streptomycin and sulfaguanidine. One week prior to admission an erythematous rash had developed, which became bullous over the face and trunk. The skin became loose and was separated in sheets. The Nikolsky sign was positive. On admission the temperature was 104 F., pulse rate 142, blood pressure 110 systolic and 80 diastolic. In addition to the eruption, there was a purulent urethral discharge and a purulent conjunctivitis. The mouth revealed superficial ulceration. The hemoglobin was 11.4 Gm., leukocyte count 9,400, with 80 per cent polymorphonuclear cells. The sedimentation rate was 63 mm. per hour, by the Westergren method. The tentative diagnosis was drug eruption (bullous erythema multiforme of the Stevens-Johnson type). Blood transfusions and other supportive measures were employed, but the patient became comatose and died a few days after admission. Postmortem examination revealed, in addition to the dermatologic changes, silicosis and an extensive retroappendical abscess. The death could not therefore be attributed to penicillin; the evidence for penicillin as the cause of death in Drs. Rabinovitch and Snitkoff's case seems to be questionable.

JOHN R. HASERICK, M.D.,
Dermatology Department, Cleveland Clinic.

## JAPANESE MEDICAL ASSOCIATION

*To the Editor:*—I wish to acknowledge with gratitude the receipt of a valued book on the history of the American Medical Association. I assure you that the volume will be a fine addition to our library, to which all our members have free access.

Not long ago your Association kindly sent to us a group of medical experts with Dr. Sensenich as its head. These gentlemen offered much useful advice and many suggestions to our medical profession in general and to our officers in particular. We were all much benefited by their association with us even though the time was limited. As President of the Medical Association of Japan I wish to extend to you and to all of your colleagues my sincerest thanks for your good will. May our mutual friendship continue through many years to come, and may our good will keep us encouraged in our humble effort to realize our goal for better medical care for our people.

AKIRA TAKAHASHI, M.D.,
President, Medical Association of Japan.

## MEDICOLEGAL ABSTRACTS

**Malpractice: Volkmann's Paralysis Following Application of Tight Bandage.**—The plaintiff sued for damages alleged to have resulted from the negligent conduct of the defendant physician. From a judgment in favor of the physician, the plaintiff appealed to the court of civil appeals of Texas, Galveston.

The plaintiff, a 4 year old boy, while playing piggy-back with his sister, fell about 2 feet to the floor and fractured his left arm just above the elbow. His mother took him to a hospital and was referred to the defendant physician who x-rayed the arm and reduced the fracture. The defendant then bound the arm in a "fully flexed" position with a tight bandage, that is, the left arm was bent so that the forearm was brought as far as it could go against the upper arm and then taped into a cone-shaped position. About 10:15 p. m. the mother discovered that the child's hand was blue and ice cold. She notified the defendant and asked whether or not the bandage could be too tight. The defendant said that the hand was all right and not to worry about it but to bring the boy in for examination the next day. The next day when the parents took the child to the defendant's office, the mother again asked the defendant about the hand being so cold and blue, and the defendant said that he thought the bandage was too tight and "snipped it a little on both sides." About two weeks later the plaintiff's mother asked the defendant why the boy was not able to move his fingers and why his hand looked sort of blue, but was told that there was nothing wrong with the hand. On August 21, over a month after the accident, the mother again called the defendant's attention to the boy's fingers. The defendant then asked her whether the boy had not been able to move his fingers and the mother told him "no" and that she thought the defendant knew. The defendant then said that it looked as if there had been some sort of nerve injury, and he called in a bone specialist. At the trial the defendant was asked, among other things, "Q. If Mrs. Bowles or Mr. Bowles had telephoned you shortly after 10:15 on the night that you set the arm, and reported to you that the hand was ice cold and blue, what would you have done? A. If I had understood that, I would have asked to see the child. I would either come over or had them meet me at the hospital, because there would be no excuse for not seeing a case that had an ice cold hand." Under the state of the pleadings, said the court, the defendant cannot be heard to urge that the plaintiff's mother did not tell him over the telephone what she said she had and it is perfectly obvious that what she told him was very simple and clear and easy to understand. For the purposes of this appeal, therefore, it must be considered that the defendant understood that the child had an ice cold hand and he did not do what he said there was no excuse for his not doing, namely, seeing the child's hand at the time he was given such information. Thus, said the court, the defendant himself furnished the expert medical testimony from which the jury could have inferred that he was guilty of negligence.

A physician's liability, said the court, is measured by the fact that he "merely engages that he has that reasonable degree of learning and skill which is possessed by others of his profession in the same locality, or by the 'average physician under the same or similar circumstances,' and that he will exercise that skill and learning with reasonable care and diligence. . . . Although required to exercise his best judgment in the circumstances, and to look for natural and probable results, if he has exercised ordinary care and diligence he is not responsible for a mistake in judgment nor for the occurrence of unexpected results which reasonably could not have been anticipated." Jurors, the court continued, in the exercise of their mere lay knowledge, cannot determine whether a physician has complied with the standard referred to. In other words, it is incumbent on the plaintiff to show by expert evidence that the defendant's negligence was a proximate cause of the plaintiff's injury, that is, that the negligent manner of treatment caused the subsequent injury to the plaintiff's hand and arm. But we have not been able to find any medical or expert evidence which would have warranted a finding by the jury that any negligence on the part of the defendant was a proximate cause of the paralysis which followed the fracture. The medical evidence bearing on the point of the proximate cause of the contracture or paralysis was that before the fracture was reduced there was no radial pulse in the boy's fractured arm, but after the fracture was reduced the pulse became palpable or noticeable. It was on this evidence that the bone specialist gave as his positive opinion that the injury occurred at the time of the fracture and as a result thereof and before it was reduced, because the circulation was stopped or cut off during the period that the radial pulse could not be found but after the fracture was reduced the circulation was restored. The medical testimony disclosed that a Volkmann's contracture may be caused by traumatic arterial spasms, thrombosis, embolism, perforation or rupture of a blood vessel and that it could have resulted regardless of any treatment given and the opinion of the bone specialist as stated previously was that it probably resulted in this instance from the original injury. There was no medical evidence which would have supported an inference by the jury that, assuming the defendant negligently permitted the arm to remain bandaged too tightly and thereby cut off the circulation, the defendant's conduct was the probable cause of the paralysis. In other words, the court concluded, there was no medical expert evidence admitted in this case to the effect that the paralysis was probably caused by the bandage applied by the defendant. The jury cannot draw medical conclusions in the absence of expert evidence. In the absence of any showing that the defendant's negligence was the cause of the paralysis in the plaintiff's arm, therefore, the court of appeals affirmed the judgment of the trial court in favor of the defendant physician.—*Bowles v. Bourdon, 213 S. W. (2d) 713 (Texas, 1948).*

**Malpractice: Expert Testimony as to Proper Fit of Denture.**—The plaintiff dentist filed suit to recover the balance of a fee due him for services in connection with the preparation of upper and lower dentures for the defendant. From a judgment in favor of the defendant, the plaintiff appealed to the Appellate Court of Illinois, Second District.

The plaintiff, a duly licensed dentist who had practiced his profession for more than twenty years, was engaged by the defendant to make an upper and lower set of dentures. The charge for these services was $200, the fairness and reasonableness of which was not disputed. After reducing the amount due to $139 the defendant refused to pay any more.

The plaintiff first contended that the defendant should not have been permitted to testify that the teeth did not fit. The evidence showed that the first lower dentures were unsatisfactory. The plaintiff made another. The defendant said that these also did not fit; that they hurt her and that she was embarrassed when eating and had to leave the table; that the teeth jumped out when she sneezed; that she took them out whenever they hurt her and did not wear them all the time. The defendant's husband testified that she slobbered at the table. Finally, at the close of her testimony, she was asked: "State whether or not these teeth did fit you or not." Over objection of the plaintiff, she was permitted to answer: "They did not fit me." The plaintiff testified that he used the most modern method and exercised the same skill ordinarily used by other dentists in making teeth; that he examined the defendant's mouth before he took the impressions for the teeth and afterward saw the teeth in her mouth and in his opinion they fit her; that when a person sneezes any false teeth plate may come out; that when a person using false teeth sneezes, the plate is loosened and may drop out; that this is no indication that teeth do not properly fit and are not properly made; that both the upper and lower teeth that he made for the defendant were properly made and properly fit her; that persons first using false teeth have some soreness as a rule; that they usually expect to make some adjustment after the teeth are first fitted to the patient's mouth, and the patient having pain does not indicate that the teeth are not properly made and do not properly fit. A licensed dentist who was called as an expert witness on behalf of the plaintiff testified that it is usual for a person who has never worn false teeth before to complain that they hurt from time to time; that in his opinion no part of the body is as tender as the tissues of the mouth; that just a little rub will cause a burn or sore mouth and a dentist has to make adjustments; that the mouth is one of the most tender parts of the body and reacts more to any kind of pressure. He also testified that the teeth in question were showed to him and he stated that the teeth looked well made, that they were in alinement; that sometimes it takes patients years to get used to false teeth and others a very short time.

In considering the plaintiff's contention, the appellate court referred to a Wisconsin decision in which the facts were very similar to those of the present case. In that case the Supreme Court of Wisconsin said: "If the plaintiff performed the dental services for the defendant and did the same in good workmanlike manner in accordance with the recognized and established practice of those in the same profession in his locality, he became entitled to the reasonable value of his services. We must hold in this case that the issue here presented was one on which expert rather than lay evidence was necessary. . . . The testimony of those familiar with that kind of work and services was all one way and to the effect that it was in accordance with the recognized standard of skill in that locality."

It will be noted, said the appellate court, that in the Wisconsin case it was held that whether the teeth fit was for expert testimony and not for the defendant alone to say that they did not fit. The defendant in the present case was allowed without objection to state that the teeth hurt her and were not satisfactory, but we think that whether they actually fit or not was a question for expert testimony, and the jury should decide whether the teeth did fit according to dental standards. The defendant offered no expert testimony on the question. The appellate court accordingly concluded that the trial court erred in permitting the defendant to state that the teeth did not fit her.

The plaintiff also contended that an improper instruction had been given to the jury. This instruction read: "The Court instructs the jury that where the buyer purchases from the seller goods to be manufactured by the seller, and it appears that the seller knows the particular purpose for which the goods are required, and where it appears that the buyer relied on the seller's skill or judgment, then there is an implied warranty on the part of the seller that the goods to be manufactured by the seller will be reasonably fit for such purpose." The point made by the plaintiff is that the sale of dentures by a practicing dentist is not the sale of tangible personal property. This question was discussed by the Supreme Court of Illinois in a case in which the question arose as to whether or not the retailer's occupation tax act applied to optometrists and the furnishing of tangible personal property such as eyeglasses to a purchaser. In that case the Supreme Court said, "If it becomes necessary for a physician to furnish medicine or surgical dressings in effecting a cure, he certainly does not thereby come within the designation of those engaged in a calling which would result in the imposition of a retail tax. The same reasoning applies to dentists even though that calling requires the furnishing of certain inlays, fills, crowns or even false teeth, if necessary to a completion of the dental service." Accordingly the appellate court concluded that the plaintiff was not engaged in selling false teeth to the defendant but that his charges were for his skill and knowledge for his personal work in the examination and making of the dentures in question. The instruction treating him as a seller of tangible personal property was therefor improperly given.

Because of errors in instruction and in the admission of evidence, the judgment in favor of the defendant was reversed. *Gunter v. Cascio, 81 N.E. (2d) 766 (Ill., 1948).*

# Council on Medical Education and Hospitals

## NEW HOSPITALS REGISTERED

The following hospitals were registered by the Council on Medical Education and Hospitals of the American Medical Association at its meeting in St. Louis Nov. 29, 1948:

Gunnison Community Hospital, Gunnison, Colo.
Escambia General Hospital, Pensacola, Fla.
Meriwether Hospital, Plant City, Fla.
Wall Hospital, Blakely, Ga.
Matthews Hospital, Dallas, Ga.
State Sanatorium, Hillcrest Division, Topeka, Kansas
Veterans Admin. Hospital, Fort Thomas, Ky.
*Mount Mary Hospital, Hazard, Ky.*
Ritchie Hospital, Cascade, Md.
Santa Maria Hospital, Cambridge, Mass.
Lynn Hospital, Detroit
Michigan Memorial Hospital, Detroit
Community Hospital, Corinth, Miss.
Memorial Hospital, Harrisonville, Mo.
Student Health Center, Lincoln, Neb.
Salvation Army Home and Hospital, Buffalo
Graylyn, Bowman Gray School of Medicine, Winston-Salem, N. C.
Cochrane Hospital, Dayton, Ohio
Cowart-Sisler Clinic-Hospital, Bristow, Okla.
Franklin Clinic Hospital, Elizabethton, Tenn.
*East Tennessee Baptist Hospital, Knoxville, Tenn.*
Cleveland Hospital, Cleveland, Texas
St. Elizabeth's Hospital, Houston, Texas
Hardy-Hancock Hospital, Jasper, Texas
Seale Clinic and Hospital, Jasper, Texas
Bayview General Hospital, Palacios, Texas
Odom Dryden Clinic Hospital, Memphis, Texas
Green Hospital and Clinic, Muleshoe, Texas
Shamrock General Hospital, Shamrock, Texas
McConnell Hospital and Clinic, Sulphur Springs, Texas
Tahoka Clinic and Hospital, Tahoka, Texas
Circle Terrace Hospital, Alexandria, Va.
Lake Chelan Community Hospital, Chelan, Wash.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc.: *Written.* July 15. Various locations. Final date for filing application is April 15. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Avenue, New York 27.

American Board of Dermatology and Syphilology: *Written.* Various Centers, Feb. 10. *Oral.* New York City, April 1-4. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: *Oral.* San Francisco, Feb. 8-10, 1949. New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Written.* Jan. 14. *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part I.* Various Centers, April and May. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* St. Louis, Feb. 18-20. Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry and Neurology: *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska:* Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 2-3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

Connecticut:* Hartford, March 8-9. Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

Delaware: *Examination.* Dover, Jan. 11-13. *Endorsement.* Jan. 20. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

Georgia: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

Hawaii: *Examination.* Honolulu, Jan. 10-13. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu 53.

Idaho: Boise, Jan. 10-12. Dir., Bureau of Occupational Licenses, Miss Estella S. Mulliner, State House, Boise.

Illinois: Chicago, Jan. 11-13. Superintendent of Registration, Mr. Fred W. Ruegg, State House, Springfield.

Indiana: *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Maine: Portland, March 8-9. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Massachusetts: *Examination.* Boston, March 8-11. Sec., Dr. George L. Schadt, 413 E. State House, Boston.

Minnesota:* Minneapolis, Jan. 18-20. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Building, St. Paul.

Missouri: Kansas City, Jan. 24-26. Sec., Mr. John A. Hailey, State Capitol Bldg., Box 4, Jefferson City.

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

Nebraska:* *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Hampshire: Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

New York: *Examination.* Various Centers, Feb. 1-4. Sec., Dr. J. L. Lochner, Jr., 23 S. Pearl St., Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, Jan. 17. Sec., Dr. Ivan M. Procter, 226 Hillsboro St., Raleigh.

Ohio: *Endorsement.* Columbus, Jan. 25 and April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Pennsylvania: *Examination.* Philadelphia, Jan. 1949. Act. Sec., Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, March 1. Sec., Mr. Luis Cueto Coll, Box 3717, Santurce.

South Dakota:* Pierre, Jan. 18-19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

Texas: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Vermont: *Examination.* Burlington, Feb. 3-5. Sec., Dr. F. J. Lawliss, Richford.

Washington:* Seattle, Jan. 17-19. Sec., Dept of Licenses, Miss Virginia Wotherspoon, Olympia.

Wisconsin:* Madison, Jan. 11-13, 1949. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls, Wis.

Wyoming: *Examination.* Cheyenne, Feb. 7. Sec., Dr. Franklin D. Yoder, Cheyenne.

---

* Basic Science Certificate required.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1931, Juneau.

Colorado: *Examination.* Denver, Mar. 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Connecticut: New Haven, Feb. 12. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

Florida: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa: *Examination.* Des Moines, Jan. 11. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Ann Arbor & Detroit, Jan. 14-15. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

Minnesota: *Examination.* April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Rhode Island: *Examination.* Providence, Feb. 9. Chief, Mr. Thomas B. Casey, 366 State Office Building, Providence.

South Dakota: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

Washington: Seattle, Jan. 12-13. Sec., Dept. of Licenses, Miss Virginia Wotherspoon, Olympia.

Wisconsin: Madison, April 2., Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted

### American J. Digestive Diseases, Fort Wayne, Ind.

**15:**253-288 (Aug.) 1948

Critique on Vagotomy, Part I. Historical and Experimental. J A. Schilling, Alexandra Feldmahn and W. J M Scott. p. 253.
Dynamics of Muscle Tonus and Its Relationship to Circulatory Failure: Part III, "New Approach to Treatment of Hypertension and Circulatory Failure by Use of Iron Salt of Adenylic Nucleotide." S. L. Ruskin.—p. 261.
Effect of Tripelennamine Hydrochloride (Pyribenzamine) on Gastric Acidity of Patients with Peptic Ulcer S A Hartman and D. M. Moore.—p. 271.
Vitamins and Hormones in Nutrition. IV. Gastro Intestinal Disease and Reduced Dietary Intake. B. F. Steve —p. 275.

### American Journal of Diseases of Children, Chicago

Evaluation of Certain Preparations for Care of Skin of Newborn Infants. M. A. Perlstein.—p. 385.

**Caudal Analgesia for Hypertension in Acute Nephritis.**—Hughes and his associates observed 2 children with acute nephritis associated with extreme hypertension and cardiac failure who failed to respond satisfactorily to administration of magnesium sulfate and other measures. Since continuous caudal analgesia had been used successfully in the reduction of extreme hypertension of obstetric patients with eclampsia, they decided to employ this method in the 2 children. Caudal analgesia was used in the treatment of 2 additional patients with acute nephritis, 1 of whom was an adult. The 3 children were in coma. Two of them had generalized convulsions and 2 uremia. The uremic children had rapidly progressive anemia. Of the 4 patients, 2 had anuria and 1 almost complete anuria. The first child responded with prompt reduction of hypertension, almost immediate recovery from coma, reestablishment of cardiac compensation and a subsequent uneventful recovery. The second child had almost complete anuria, uremia, rapidly progressive anemia, extreme hypertension, cardiac failure and generalized convulsions. She responded to continuous caudal analgesia with a prompt reduction of hypertension, but the effect could be maintained for only an hour. She died. The third patient, a diabetic adult with acute nephritis, had total anuria, moderate uremia and moderate hypertension. The hypertension was repeatedly reduced with caudal analgesia, but the procedure seemed to bear no influence on subsequent diuresis, which may have been increased by other types of treatment given. The fourth patient, a child, had total anuria, uremia, rapidly progressive anemia, hypertension, cardiac failure and generalized convulsions. Moderate diuresis followed immediately the institution of continuous caudal analgesia, and the blood pressure was repeatedly reduced. However, the patient died. The mechanisms with which continuous caudal analgesia effects reduction in hypertension are believed to be increased blood flow to the lower extremities, probable dilation of the splanchnic bed and increased blood flow to the kidneys, possibly with resultant diminished production of renin. The use of continuous caudal analgesia may prove valuable for patients with severe acute nephritis who, in spite of the use of magnesium sulfate and other measures, continue to have extreme hypertension, cardiac failure or hypertensive encephalopathy. Hypertension in 2 additional cases of acute nephritis with severe cardiac failure has responded to continuous caudal analgesia.

**Congenital Diabetes Insipidus Resistant to "Pitressin."**—Dancis and his collaborators report the case of an infant in whom the presenting problem of recurrent bouts of unexplained fever was demonstrated to be secondary to dehydration resulting from extreme polyuria. It was believed that the polyuria was not due to deficiency in neurohypophysial activity, because (1) the polyuria did not respond to the administration of "pitressin" and (2) an antidiuretic substance presumably derived from the pituitary was present in the patient's urine in large amounts. The excessive diuresis in this patient may be due to a congenital anomaly of renal function resulting in a kidney unable to respond to normal hormonal control.

**Salmonella Meningitis.**—The recent occurrence in Gorgas Hospital of the Panama Canal Zone of meningitis due to Salmonella in 2 infants, 1 of whom recovered, prompted Henderson to review the hospital's clinical and laboratory records back to 1925. The search revealed a third case. The reviews of the literature revealed a total of 144 cases, the first report having appeared in 1907. The author's extensive bibliography contains 81 references. He believes the disease to be septicemia, with locus minoris resistentiae an important factor. Certain few types of Salmonella account for the majority of the cases. A combination of factors peculiar to newborn infants operates to make them especially susceptible to the infection. The clinical features for that group include an epidemic tendency, diarrhea and a rapidly fatal course, in contrast to sporadicity, common absence of diarrhea and better prognosis in older infants. In both groups the course is febrile, with leukocytosis. The spinal fluid shows an increase in cells, with an early predominance of neutrophils. The organism may often be seen on direct smear and is identified from cultural and serologic characteristics. At necropsy purulent meningitis is observed. The disease is favorably influenced by systematic treatment with sulfonamide compounds, sulfadiazine probably being the drug of choice. Of 19 patients treated in this manner, 10 recovered, while only 8 of 128 patients who did not receive a sulfonamide drug recovered. Penicillin is ineffective. The usefulness of streptomycin remains to be investigated. Blood transfusion appears to be a valuable aid. Prognosis also depends on the age of the patient and the type of organism causing the infection. Only 1 of 49 patients less than 1 month old recovered, whereas 17 of 80 children in the older age group lived. Patients with infections due to Salmonella paratyphi A, S. paratyphi B and Salmonella panama accounted for the majority of those who recovered, while 45 persons with infections due to Salmonella enteritidis and its varieties all died.

**Systemic Aleukemic Reticuloendotheliosis (Letterer-Siwe Disease).**—Varga and his associates say that although Letterer described a special type of reticuloendotheliosis in a young child almost twenty-five years ago, few cases have been reported since. The authors present the histories and necropsy reports of 3 young children with systemic aleukemic nonlipid reticuloendotheliosis recently studied by them. Two of the children exhibited cutaneous manifestations not unlike infected eczema. Emphasis is placed on the presence of these cutaneous lesions. Cutaneous lesions apparently are an essential part of the disease. Most reports identify them as petechial or purpuric, but the authors say that lesions similar to those described in their cases have also been mentioned in the literature. Infections, especially purulent otitis media, are mentioned in many cases. The following signs are listed as characteristic of

Letterer-Siwe disease: severe splenomegaly with moderate enlargement of the liver, a hemorrhagic tendency, with petechiae of purpura; a generalized glandular enlargement, localized tumors of bone (rarefactions), secondary anemia, fever and generalized hyperplasia of the reticuloendothelial system. The condition known as Letterer-Siwe disease may be less infrequent than supposed in the past. The authors believe that the clinical similarity to commoner diseases, such as infantile eczema, and its pathologic similarity to many other granulomatous diseases may have confused the diagnosis in the past. Antibiotic drugs failed in the reported cases and irradiation was not tried.

**Lead Orthophosphate and Roentgen Rays in Bone Metastases.**—A review of the literature convinced Reynolds and his co-workers that colloidal lead orthophosphate, introduced by Ullmann and Bischoff, is considerably more stable and less toxic than the electric suspension of metallic lead used by Bell for the treatment of cancer. Diffraction studies performed in rabbits at Harper Hospital confirmed the affinity of the lead for the osseous system, the largest deposition occurring along the epiphysial lines. The intravenous injection of colloidal lead orthophosphate in conjunction with roentgen therapy leads to a threefold effect in the malignant neoplastic invasion of the osseous system: (1) The lead has a certain toxic action in itself; (2) there is a direct destructive effect of the roentgen ray, and (3) the heavy lead atoms deposited within the tumor area emit, under the influence of the roentgen irradiation, ionizing secondary electrons which also act on the carcinoma cells. The method has been used during the past twenty years in a series of 355 cases of bone metastases chiefly from carcinoma of the breast. In 95 per cent of the cases the immediate palliative effect was remarkable. The average survival amounted to three years. In 4 per cent the survival was more than five years. More recently attempts were made to use radioactive lead orthophosphate to add internal irradiation, if possible, to the enumerated threefold effect. In a series of preliminary experiments tracer studies were carried out in rabbits and some patients by injecting a specially prepared colloidal solution of the lead orthophosphate in which the phosphorus was "tagged." The results substantiated the findings arrived at by chemical and roentgen diffraction analysis. Investigations with "tagged" lead are necessary before worthwhile therapeutic efforts can be undertaken.

Exophthalmos and Thiouracil Therapy. W. H. Beierwaltes.—p. 364.

Lobar Adenocarcinoma of Lung Simulating Pneumonia: Report of 2 Cases. Gertrude Silverman and A. Angrist.—p. 369.

**Pancreatic Calcification.**—The objectives of the analysis presented by Gambill and Pugh were (1) to study the symptoms and the roentgenologic features in cases of pancreatic calcification and (2) to learn whether there is any correlation between the extent of calcification in the pancreas and the incidence of clinical manifestations, with particular reference to the manifestations of other complications of pancreatic disease such as diabetes mellitus and steatorrhea. There were 39 cases in which, in the opinion of one of the authors, the criteria for the roentgenologic diagnosis of pancreatic calcification were fulfilled. They found that calcareous deposits in the pancreas were usually but not always associated with relapsing pancreatitis. Commonly the symptoms were those of pancreatitis, although in approximately two fifths of the cases there was either no history of pancreatitis or a doubtful one. Among cases in which a definite history of pancreatitis was obtained calcification became evident in a fifth in one year after the onset of pain, but in another fifth calcification was not discovered until after eleven to twenty-two years. Associated complications in the order of frequency of occurrence were diabetes, steatorrhea, gastrointestinal hemorrhage, morphinism, pancreatic pseudocyst, pancreatic abscess and peripheral neuritis. There was a high degree of positive correlation between the extent of pancreatic calcification and the incidence of two other complications associated with pancreatic calcification, diabetes and steatorrhea. Diabetes and steatorrhea occurred only in cases of calcification in which there was a definite diagnosis of pancreatitis.

**Mixed Infection in Subacute Endocarditis.**—Olinger reports 2 cases of subacute bacterial endocarditis with mixed infection which responded favorably to antibiotic therapy. In the first case Corynebacterium pseudodiphthericum (hoffmannii) and Streptococcus viridans were present, the former having higher resistance to penicillin than the latter. When Corynebacterium was recognized as one of the infecting agents, penicillin was given in adequate dosage. In the second case Str. viridans and Hemophilus parainfluenzae were present. The simultaneous use of two antibiotics, penicillin and streptomycin, was necessary. This represents the third reported case of subacute bacterial endocarditis due to a gram-negative bacillus which was successfully treated with streptomycin. It is suggested that mixed infection in subacute bacterial endocarditis may be more frequent than is reported. Adequate selection of suitable antibiotics may require identification of all the organisms involved in a given infection.

**Reduction in Arterial Hypertension by High Spinal Anesthesia.**—This is the seventh of a series of reports on the effect of spinal anesthesia on hypertension. It is the first of several devised to elucidate the mechanism of the fall of arterial pressure produced by spinal anesthesia. Simultaneous arterial and venous pressures were determined in 5 normotensive subjects. Twelve separate studies were made in 10 patients with a clinical diagnosis of essential hypertension. Control observations were made, and similar determinations were then made with high spinal anesthesia induced by 150 mg. of procaine hydrochloride. Observations were continued during recovery stages. In the majority of the patients with essential hypertension, the arterial pressure fell before the venous pressure fell. In 1 case, the venous pressure fell without any significant decrease in arterial pressure. In only 2 cases, the venous pressure dropped first, and in these 2 cases the arterial pressures fell to their lowest levels before the venous pressures fell to their lowest levels. In these 2 cases, the arterial pressures were rising while the venous pressures continued to fall. There is no constant time correlation between the falls of arterial and venous pressures during high spinal anesthesia in patients with hypertensive disease. It is extremely unlikely that decreased venous return and diminished cardiac output are the causes of the fall in arterial pressure caused by high spinal anesthesia in either normotensive or hypertensive subjects. The failure of these data to support the idea that decreased cardiac output is the cause of falls in arterial pressure gives additional support to the likelihood that these falls in arterial pressure are caused by interruption of vasomotor function.

**Tonsillectomy—Pro and Con.**—Gaddy believes that tonsillectomy and adenoidectomy are indicated in children in whom hypertrophy causes obstruction with labored breathing. Tonsillectomy, after one or more attacks of peritonsillar abscess or quinsy, will prevent recurrences. Tonsillitis followed by systemic infections, such as acute rheumatic fever, endocarditis or nephritis, should be treated by tonsillectomy as soon as the acute attack of the complicating infection subsides. Routine removal of tonsils and adenoids in children is to be condemned because of subjecting the child to the risks of surgical treatment without benefit of improved health. In many cases, when normal tonsils and adenoids have been removed, the child's general condition becomes worse. This occurs because the common cold that is acquired in childhood, instead of becoming an ordinary infection of the upper respiratory tract, results in acute bronchitis, or bronchopneumonia or lobar pneumonia. This is due to the absence, or break in the protective ring, of lymphoid tissue in the pharynx and throat. The immediate postoperative complications are bleeding, pneumonia, acute otitis media, suppurative cervical adenitis, atelectasis, tetany, erysipelas and lung abscess. The author presents a photograph which illustrates the method which he has used for the past seven years for the prevention of postoperative complications after tonsillectomy. He uses postural drainage so that blood and saliva are not aspirated, and postoperative pneumonia and lung abscess are thus prevented. The relation of poliomyelitis and tonsillectomy during the months of July to October, inclusive, shows that the possibility of concurrence is minimal, but when it does occur it is generally of the serious bulbar type. The Board of Preventive Medicine advises physicians not to perform tonsillectomies when poliomyelitis epidemics occur during these months.

**Isolation of Mumps Virus.**—The Henles and their associates were concerned with the isolation of mumps virus from the saliva of human beings at various stages of infection. It was considered difficult to approach these problems under epidemic conditions, since frequently the time and intensity of exposure would not be accurately known, whereas the study of persons experimentally exposed to mumps virus offered the advantage of controlling both these factors. Exposure of 15 children to mumps virus of fifth amniotic passage in chick embryos led to involvement of the salivary glands in 6, orchitis in the absence of other manifestations of mumps in 1 and no signs of illness in 8. Attempts to isolate virus from the saliva of these persons gave the following results: 1. All patients with involvement of the salivary glands excreted virus beginning on the eleventh to fifteenth day after exposure, two to six days prior to onset of clinical signs of disease and extending up to the fourth day of illness. 2. The patient with primary orchitis without any recognized involvement of the salivary glands excreted virus for two days, beginning on the fifteenth day after exposure and ten days prior to his illness. 3. Six of the 8 children classified as having inapparent infections because of their serologic response in the absence of clinical signs of illness began to excrete virus on the fifteenth to sixteenth day after exposure for one to nine or more days. The epidemiologic significance of these data is discussed.

**Hr Blood Factors as Cause of Transfusion Reaction.**—According to Wiener, Rh-positive persons can be isosensitized because of the existence of more than one variety of Rh factor and the so-called Hr factors. Luckily, these other blood factors are far less antigenic than the original rhesus factor ($Rh_0$) so that such cases are rather rare. When isosensitization does occur it hardly ever reaches the degree characteristic of $Rh_0$ or A-B sensitization, so that the antibodies usually are not demonstrable in the sensitized person's serum and the reactions following transfusions of incompatible blood are mild and simulate pyrogenic reactions. These minor hemolytic reactions occurring in Rh-positive recipients are the subject of the present paper. The cases forming the basis of this study were derived principally from the Blood Transfusion Division of the Jewish Hospital of Brooklyn. The author lists 32 cases of post-transfusion febrile reactions. In cases 1 to 22 there was some clinical evidence of post-transfusion hemolysis, while in cases 23 to 32 there was no evidence of hemolysis. While the distribution of the Rh-Hr among the control cases (cases 23 to 32) did not seem unusual, the distribution among the patients who had hemolytic reaction deviated strikingly. One cannot avoid being impressed by the large proportion of Hr-negative patients in the series—14 $Rh_1Rh_1$ and 3 $Rh_2Rh_2$ out of 22 cases. These results suggest that sensitization to the Hr factors, hr' and hr", must have played a role in many of the reactions. Hr antibodies were clearly demonstrable in the serums of only 3 (2 anti-hr' and 1 anti-hr") of the 17 presumably sensitized patients. This indicates that Hr sensitization, when it occurs at all, is usually mild. That such reactions may occasionally endanger the life of the patient is demonstrated by the fact that 1 of the 3 patients with demonstrable antibodies died. While routine pretransfusion Hr typing is still not practicable, one should at least investigate every febrile reaction for evidence of hemolysis. If hemolysis has occurred even though the patient is Rh positive, Hr tests should be done, and if the patient is found to be Hr negative, only Hr-negative blood of a compatible blood group should be used for future transfusions. If Rh-negative patients have reactions despite transfusions of type Rh blood, one should search for other sensitizations, particularly against the M factor. Eventually blood transfusion practice should include precautions to avoid sensitization against the Hr factors as well as the Rh factors, particularly in the case of women, in order to avoid the birth of babies with erythroblastosis caused by Hr sensitization.

**Nitrogen Mustard in Hodgkin's Syndrome.**—Zanes and his associates report on 31 patients with Hodgkin's disease who were treated with a total of 44 courses of methyl-bis (beta-chloroethyl) amine hydrochloride. Each patient was given 0.1 mg. of the nitrogen mustard per kilogram of body weight for five days with the exception of the 7 patients who were given a double dose on two consecutive days and a single dose on the third day. Each dose was dissolved in 10 cc. of isotonic sodium chloride solution and injected immediately via the tube through which isotonic sodium chloride solution was being administered intravenously to the patient. From 200 to 500 cc. of isotonic sodium chloride solution was infused during each injection of the nitrogen mustard. Beneficial results were observed in 20 patients receiving twenty-four courses. Indirectly, 3 other patients benefited through an apparent resensitization to roentgen rays. Improvement was characterized in most instances by immediate disappearance of fever, itching and pain. Brownish pigmentation of the skin was observed to decrease in several cases as did Hodgkin's skin lesions, splenomegaly, hepatomegaly and adenopathy. The toxic effects of the hydrogen mustard on hemopoietic and lymphoid tissues as reflected in peripheral blood and sternal marrow changes are described and discussed. These changes are contrasted with hematologic alterations observed during Hodgkin's disease. Nausea and vomiting was observed consistently after nitrogen mustard therapy. Unusual complications include ulceration and perforation of the mucosa of the gastrointestinal tract. Skin lesions macroscopically similar to those frequently seen in Hodgkin's disease appeared in an unusually large number of cases following nitrogen mustard therapy.

**Effect of Feeding Propylthiouracil and Cholesterol on Arterial Intima.**—According to Horlick and Havel previous work demonstrated that thyroidectomy renders animals more susceptible to the cholesterolemia and atherosclerosis which follow the feeding of cholesterol. Feeding desiccated thyroid or potassium iodide seems to protect the animals against the development of cholesterol-induced lesions and lowers the blood cholesterol levels. The authors were able to confirm the protective action of desiccated thyroid in another species, the chicken. They also observed the synergistic effect of cholesterol and thiouracil on raising the blood cholesterol levels of the chicken. With these considerations in mind, they decided to use the antithyroid drug thiouracil in the rat in an attempt to break down the resistance of this species to the induction of atherosclerosis by feeding of cholesterol. They found that propylthiouracil did not succeed in breaking down the rat's resistance to cholesterol-induced atherosclerosis. The resistance to atherosclerosis in this animal is probably dependent on other factors in addition to the thyroid gland and its secretions.

**Methyl Hydantoin ("Mesantoin") in Epilepsy.**—David and his co-workers tried the new anticonvulsant drug methyl hydantoin, called "mesantoin," for periods as long as eight months in the treatment of 20 patients with epilepsy. Eleven patients had grand mal seizures, 5 had petit mal epilepsy, 3 had both grand mal and petit mal attacks and one had jacksonian epilepsy. Administration of methyl hydantoin proved more effective in grand mal than previously used drugs in 7 of 11 patients. The number of petit mal attacks was decreased in each of the 16 patients suffering from this condition. *Inconclu-*

sive results were obtained in the 3 patients with both grand mal and petit mal because the period of observation was too brief. Dermatitis was caused by the drug in 3 patients; 1 patient complained of gastritis; another experienced an episode of toxic psychosis following administration of only four tablets, and 10 patients noted stimulatory effects. The authors believe that methyl hydantoin is an effective drug in the treatment of grand mal epilepsy and is especially useful in those cases in which phenobarbital causes undue mental depression or in which either phenobarbital or diphenylhydantoin sodium is ineffective. It appears somewhat more effective in the treatment of petit mal than diphenylhydantoin and should be given clinical trial in those cases of either grand mal or petit mal epilepsy in which other drugs are ineffective or not tolerated.

**Obesity Following Cerebral Injury.**—Pisetsky and Roswit present the case of a man, aged 51, who in a few months following a head injury gained 246 pounds (111.6 Kg.) in weight. The lesion was referred to the area of sella turcica. There was no evidence of any other metabolic disorder. The authors discuss the hypothalamic-pituitary system in relation to the possible role in the production of obesity.

**Cholesterol in Coronary Arteriosclerosis.**—Steiner demonstrated that arteriosclerotic lesions in young dogs similar in distribution and morphologic characteristics to human arteriosclerosis resulted from prolonged hypercholesterolemia. High serum cholesterol values were produced by the feeding of 10 Gm. of cholesterol daily to dogs whose thyroid function was modified by administration of thiouracil. Additional experiments showed that choline was effective in preventing arteriosclerosis in cholesterol-fed rabbits for a limited period, and in some instances caused a reabsorption of the previously induced arteriosclerotic lesions. Repeated consecutive determinations of serum cholesterol for periods up to two years in 15 patients with coronary arteriosclerosis, in 15 relatively normal persons, and single serum cholesterol determinations in 50 additional patients with coronary arteriosclerosis and in 50 normal persons of the same age group revealed that the serum cholesterol level of patients with overt coronary arteriosclerosis is significantly higher than the serum cholesterol level in normal persons in the same age groups. In addition, the serum cholesterol level of patients with coronary sclerosis fluctuates widely. An attempt to evaluate the significance of the cholesterol content of the diet in 14 patients with coronary arteriosclerosis has been made. It has been shown that within the limits of this study varying the cholesterol content of the diet fails to produce significant alterations of the serum cholesteral levels. Preliminary results indicate that large amounts of dietary cholesterol can be absorbed from the gastrointestinal tract without alteration of the serum cholesterol or clinical evidence of cholesterol deposition in the tissues. Further studies in cholesterol metabolism using tagged atoms are needed.

**False Serologic Reactions for Syphilis.**—Moon-Adams examined 470 infants of treated syphilitic mothers within the first three months of life for serologic, clinical and roentgenologic evidence of syphilis. False positive serologic reactions were observed in 69 of 146 infants (47.3 per cent) tested in the first month of life, in 16 of 232 infants (6.9 per cent) tested in the second month of life and in 1 of 87 infants (1.2 per cent) tested in the third month of life. False negative reactions were observed in 5 of the 470 infants (1.0 per cent of the total). In 1 of these syphilis was probably acquired. The duration of false positive serologic reactions varied from twenty-four days to fourteen weeks. Of the total 86 infants with false positive serologic reactions, 31 (36 per cent) had become negative in reaction in four weeks; 64 (74 per cent) in eight weeks; 80 (93 per cent) in twelve weeks, and 84 (97.7 per cent) in fourteen weeks. Correlation of the number of false positive serologic reactions with the time of mother's treatment shows a higher percentage in the infants of mothers treated in the last trimester of pregnancy. Compared with statistics based on mothers treated with arsenicals and bismuth compounds, a greater number of false positive serologic reactions can be expected in the infants of mothers treated with penicillin. In cases of mothers who have secondary syphilis during pregnancy and who receive treatment in the eighth month of pregnancy, it seems highly probable that the false positive reaction of the infants is not properly termed "false" but is evidence of a treated syphilitic infection contracted and cured in utero. In cases of mothers who were treated prior to pregnancy and received no treatment during pregnancy, it seems probable that a positive serologic reaction in the infant, which reverses to negative, represents a transfer of the reagin of the mother's blood. If these possibilities are accepted, the so-called false positive serologic reaction of the newborn infant has a dual cause.

**Cancer of Respiratory System in Chromate-Producing Industry.**—Machle and Gregorius point out that in 1947 the management of one of the large producers of chromates in the United States became concerned with the incidence of lung cancer among their employees. An analysis of the mortality data of this company established the existence of high rates for lung cancer among the workers. A study was initiated by the health committee of the plants engaged in the extraction of chromates from ore. Of all deaths in the chromate industry 21.8 per cent were reported as being due to cancer of the respiratory system. This ratio is sixteen times the expected ratio of 1.3 per cent. The crude death rate for cancer of the lung was twenty-five times the normal. In five of the six plants investigated the death rate for lung cancer in the group 50 years of age and under ranged from twenty to seventy times that for a comparable industrial group. The mortality rates for lung cancer at ages over 50 years ranged from ten to forty times that for a comparable industrial group. There are no convincingly significant abnormalities in the rates for cancer in sites other than the lung. It appears that the problem in the chromate industry is limited to the cancers of the respiratory system. Sixty-six of the 193 deaths were due to cancer and 42 of these deaths were from cancers of the lung. One plant handling only bichromates, chromic acid and a tanning compound had 33 deaths, none of which was due to cancer of the respiratory system. This experience suggests that the monochromates may be the compounds responsible for cancer of the lung.

**Intravitreous Streptomycin.**—Gardiner and his associates say that previous studies have shown that streptomycin does not easily penetrate through the cornea. An attempt was made to investigate the concentrations of the drug attained in ocular fluids following its administration (1) into the vitreous and (2) subconjunctivally. An investigation of the action of streptomycin on the eye tissues following its intravitreous administration was also undertaken. Two samples of streptomycin were used. The pure sample was used for the intravitreous toxicity tests; it was streptomycin hydrochloride calcium chloride double salt. For the diffusion experiments the second sample of commercial streptomycin was used. For the diffusion experiments 2,000 micrograms of streptomycin was injected into the vitreous in 0.1 cc. of sterile isotonic sodium chloride solution. For the toxicity experiments two doses were used, 1.2 mg. and 3.0 mg., injected in 0.1 cc. isotonic sodium chloride solution. In these latter experiments the eyes were observed at regular intervals for twelve to one hundred and twelve days and the changes noted. The eyes were then removed and examined histologically. It was found that intravitreous injection of 2,000 micrograms of streptomycin acts as a depot from which streptomycin diffuses away slowly, chemotherapeutic concentrations still being present in the ocular fluids after three days. This slow rate of diffusion of streptomycin suggests that a single intravitreous injection of streptomycin might well be sufficient to deal with certain ocular infections in man. On the other hand, the present investigations revealed clearly that even 1.2 mg. of pure streptomycin produces serious and permanent retinal damage.

**Subconjunctival Penicillin in Infected Corneal Ulcers.**—Rizk resorted to subconjunctival injections at a time when there was a shortage of penicillin in Egypt. Patients dislike subconjunctival injections. Two instillations of 1 per cent tetracaine hydrochloride solution at three minute intervals while the eyes are closed are harmless to the epithelium and produce sufficient anesthesia to allow the prick of the needle to be done almost painlessly. Apart from the prick of the needle, the mere infiltration of fluid under the conjunctiva causes some pain. This pain can be easily abolished if 1 per cent procaine hydrochloride solution in nonpyrogenic distilled water is used instead of simple distilled water in the preparation of penicillin solution. A concentration of 20,000 units per cubic centimeter was found to be satisfactory in cases in which 10,000 units per cubic centimeter was not satisfactory. To a bottle of 100,000 units of crystalline penicillin salt, 5 cc. of 1 per cent procaine hydrochloride solution in distilled nonpyrogenic water was added, and 0.5 cc. was injected subconjunctivally twice daily. The eye is opened and partially fixed by a pair of Desmarres' retractors applied to the lids with their tips introduced into the fornices if the patient is unable to open and fix his eye while the injection is being given subconjunctivally at a distance of 2 to 3 mm. from the limbus. Ten injections are usually sufficient, and after that hot fomentations can be used. This method of treatment yields better results than the older methods, in which general sulfonamide therapy or foreign protein therapy formed a part of the treatment.

**Angiocardiography in Congenital Heart Disease.**—Keele points out that as surgical methods of treatment have become available for patent ductus arteriosus, coarctation of the aorta and Fallot's tetralogy, the problem of accurate diagnosis of congenital heart disease has assumed increasing importance. Angiocardiography provides a method whereby this necessary accuracy may be obtained. The shapes of the cardiac chambers differ in some respects from the anatomic descriptions founded on dissections of the cadaver. Reasons for these differences are suggested. Examples of abnormal angiocardiograms in a variety of congenital heart lesions are shown to illustrate the diagnostic value of the method. The author believes that angiocardiography should be used in any case of congenital heart disease where operation is being considered, as with patent ductus arteriosus and coarctation of the aorta, since it may not only provide proof of the suspected lesion but also reveal others.

**Technic of Angiocardiography in Congenital Heart Disease.**—According to Brocklebank, angiocardiography signifies an advance in the accurate diagnosis of congenital heart disease. The described method demonstrates that this is practicable with standard roentgenographic apparatus. Considerable improvement in technic and in the diagnostic value of the method can be expected as special accessories are developed and as more of the factors are more fully understood. Much yet remains to be explained in the appearances shown in the roentgenograms, and interpretation will improve with experience and as the results are compared with the findings of cardiac surgery. As at present practiced the method appears to be a safe and useful diagnostic procedure.

*A Fatal Case of Myelitis After Antirabic Vaccine. I. Ansell.—p. 338.

**Fatal Myelitis After Antirabic Vaccine.**—Ansell reports the case of a soldier, aged 26, who was serving in India. He had been well until a few days before his admission to hospital on July 9, 1946, when he first complained of fever and pains in his limbs. He had been bitten by a healthy puppy fourteen days previously, and had received twelve antirabic injections, starting two days after the incident. The dog was said to be still healthy and the course was thereupon stopped. The author presents a detailed clinical history and a necropsy report and says that this was not a case of rabies but probably of polyneuritis or myelitis due to the antirabic vaccine, the former being less likely in view of the absence of sensory changes. An alternative cause for the ascending myelitis could be acute anterior poliomyelitis, particularly as the latter is endemic in this part of India. In the reported case, killed carbolized vaccine was given, and skin sensitivity in the form of prominent reactions at the sites of inoculation was manifested. The balance of evidence would seem to be in favor of acquired anaphylaxis as the causation in this case. Antirabic treatment should be given only when the correct indications are present. A healthy dog should be kept under observation for the usual ten days before treatment is begun, except, possibly, in cases of severe bites on the face. A family or personal history of allergy indicates the need for preliminary skin tests for sensitivity, and if excessive local reactions occur during treatment the desirability of desensitization should be considered. If the neuroparalytic complications have already made their appearance, then, in view of the serious prognosis, especially in the Landry type, it would be worth while to try out the effect of antihistamine drugs on the basis of the allergic theory. An iron lung should be available in case of respiratory failure. The usual precautions during antirabic treatment—avoidance of unnecessary exertion and of alcohol, and provision of adequate rest—should be strictly enforced.

*Why is it That Vaccination Increases the Incidence of Diphtheria in Nonvaccinated Persons? The Clue to An Enigma. R. Rendu.—p. 617.
Hazards of Cold Permanent Waves. P. J. Michel and J. Saint-Paul.—p. 625.

**Vaccination and Increased Incidence of Diphtheria.**—According to Rendu, French, Danish, Italian and Polish statistics of children in seven towns of these four countries show that during the period 1905 to 1933, when antidiphtheritic vaccination was not yet practiced, diphtheria occurred in 2,182 of 645,327 children; i. e., a morbidity rate of 3.38 per thousand per year. During the period 1935 to 1946, when antidiphtheritic vaccination was practiced on a large scale, diphtheria occurred in 2,568 of 644,010 vaccinated or unvaccinated children, a morbidity rate of 3.98 per thousand per year; diphtheria occurred in 1,684 of 154,321 unvaccinated children, a morbidity rate of 10.9 per thousand per year, and in 884 of 489,689 vaccinated children, a morbidity rate of 1.8 per thousand per year. Thus in these seven cities where three quarters of the children had been vaccinated, the average incidence of the disease among the unvaccinated seems to be three times higher after vaccination had been practiced on a large scale than before it was practiced, while the total morbidity rate has not been reduced. These paradoxic phenomena may be explained by incorrect statistical technics which do not take into consideration important facts such as epidemic bouts caused by the influx of new contingents of the population, influence of the seasons on the incidence of diphtheria and influence of the age of the children. The first injection of diphtheritic anatoxin renders the children hypersusceptible to the disease because of the reduced resistance of the organism resulting from the vaccinal shock. Vaccinated and unvaccinated persons must be compared with one another during the same lapse of time in order to provide statistical data of value. A large number of unvaccinated children represent those in whom vaccination was contraindicated by acute or chronic pathologic conditions, and who, therefore, are most susceptible to diphtheria. These statistical errors are responsible for the increased incidence of diphtheria in the unvaccinated children and for the drop in the incidence in the vaccinated.

*Anatomicopathologic Observations on Cadavers of Patients Treated with Urethane. E. Letterer.—p. 385.
*Treatment of Non-Leukemic Diseases, Particularly of Lymphogranulomatosis with Urethane. H. E. Bock.—p. 390.
Experimental Investigation on Effect of Urethane on Phagocytosis, on Stellate Cell Storage and on Inflammation. W. Masshoff, W. Heinzel, G. D. von Rom and M. Siess.—p. 397.
Regulation of Albuminous Substance in Plasma. IV. Report. Plasma Albumin and Typhoid Fever. H. Pickert.—p. 400.

**Postmortem Studies After Treatment with Urethane.**—Letterer reports necropsy studies on 2 men aged 60 and 69 treated with urethane for lymphogranulomatosis, on a woman aged 59 treated with urethane for hypernephroma and on a man aged 67 treated for leukemic myelosis. Death resulted from pneumonia in all cases, from lobar pneumonia in 1 and from terminal bronchopneumonia in 3. The aleukocytic character of the microscopic picture of the pneumonias was striking; in addition there was noted a large number of causative agents in the alveoli of the lungs. The deficient formation of granulocytes was probably responsible for the weakening of the leukocytic defense, for the spread of the causative agent and for the atypical course of the pneumonic infiltration. Pneumonia with agranulocytosis is a reaction likely to result from treatment with urethane. The drug is responsible for the atrophy of leukocytes in normal lymph nodes and in those affected by lymphogranulomatosis. There is a simultaneous collagenization of the reticular fibers and a fibrosis of the entire lymph node; thus the lymphogranuloma becomes obliterated. The lymphocytes in the follicles of the spleen disappear and there is a simultaneous numerical decrease of nuclei in the pulp and a thickening of the sinus walls. There is no general decrease in the cells of the bone marrow; the maturing segmental forms disappear, while the number and the shape of the primary forms remain unchanged in the normal and in the leukemic marrow.

**Urethane in Nonleukemic Diseases.** — Bock treated 6 patients with lymphosarcomatosis by oral or rectal administration of 4 to 6 Gm. of ethyl urethane daily. In 5 of these patients there was only a temporary regression of the enlargement of the lymph nodes and of the spleen. Satisfactory results were obtained in 1 case of round cell sarcoma, but it is still too early for definite conclusions. Irradiation therapy may be omitted only in cases in which rapid improvement takes place. The treatment of malignant tumors with urethane failed most frequently because of the subjective and objective intolerance of the drug. The granulopoiesis was very sensitive to the drug in all cases. More satisfactory results were obtained in 8 cases of lymphogranulomatosis in 4 men and 4 women. Fresh cases with atypical proliferation of reticulum cells and with considerable capillarization showed the best and most rapid response. There was, however, no definite recovery which would have made further treatment with urethane dispensable. Granulopoiesis required constant control. Functional agranulocytosis may precede numerical neutropenia. The patient should be treated with penicillin and "de-ma," a preparation containing a mixture of equal parts of methylsulfapyrimidine and of 4-aminomethylbenzene sulfonamide salt of sulfathiourea. A sudden drop in erythrocytes requires discontinuation of urethane. With increased proliferation, the erythropoiesis also becomes sensitive to urethane although to a lesser extent than the granulopoiesis. Urethane is poisonous for mitosis, but its predominating toxic effect is on the metabolism of the nuclei by attacking proliferating cells in various phases. In this process a substance may be produced which causes the disappearance of megaloblasts and the appearance of reticulocytes in the periphery. Urethane also attacks the protoplasm in the ferment systems, and this effect may be manifested by peroxidase clots in granulopoietic cells. The effect of urethane is reflected only inadequately in the total consumption of oxygen by the bone marrow and blood.

*Leukemia and Salmonellosis (S. Dublin). W. H. H. Tegelaers, G. M. H. Veeneklaas, A. Clarenburg and H. H. Vink.—p. 1919.

**Leukemia and Salmonellosis (S. Dublin).**—Tegelaers and his associates present the case of a 2½ year old child, daughter of a stock breeder, who had acute lymphatic leukemia and salmonellosis. Bacteriologic examination of the blood revealed Salmonella dublin. The agglutination titer of the patient against this type of organism was 1 : 1,600. The feces also contained S. dublin. Since S. dublin occurs frequently in cattle, an examination was instituted to ascertain whether the salmonella infection in the child was in any way connected with a germ carrier in the cattle. A cow was found to excrete regularly with the feces a large number of S. dublin organisms. It may be assumed that the salmonellosis in the little patient had arisen secondarily to the leukemia.

*Antituberculosis BCG Vaccination in Cordoba, Argentina. G. Sayago, A. Chattas and A. P. H. Degoy.—p. 1425.
Typhoid Fever: Complications. Statistical Study of 1300 Cases. H. Rugiero, L. Charosky and H. Galli.—p. 1435.

**BCG Vaccination.**—Sayago and collaborators report on a large group of infants and children given BCG vaccination and a large group of infants and children who were not given the vaccination. The general mortality within the first year of life reached 8.3 per cent among the vaccinated and 15.6 per cent among the control group. A weak degree of tuberculin sensitivity was prevalent among the vaccinated in contrast to the strongly positive results of Mantoux's test eventually found in children belonging to the control group. Chest roentgen examinations performed on the vaccinated group disclosed 57.5 per cent of lesions among children with tuberculous contact and 18.9 per cent among the noncontacts, while in the control group there were 74.3 per cent of lesions in children exposed and 47.6 per cent in the noncontacts. In addition the roentgenograms in the vaccinated group proved to be less important than the ones seen in the nonvaccinated children, especially in the case of primary infection when the sole lymph node enlargement could be detected in the former.

*Streptomycin in Abdominal Tuberculosis in Children. R. Matte, S. Ibáñez and A. Trautmann.—p. 371.
*Poliomyelitis: Epidemiologic and Sanitary Aspects. H. Romero and R. Armijo.—p. 389.

**Streptomycin in Abdominal Tuberculosis.**—Matte and his collaborators gave streptomycin to 10 children, between the ages of 6 and 12 years, with intestinal, peritoneal or both forms of tuberculosis. The disease was acute in all cases. It complicated pulmonary tuberculosis in some of the cases. The drug was administered in daily doses of 1 Gm. for the first and 0.5 Gm. for the second month. In some cases the treatment lasted for three consecutive months on the same dose schedule. The daily dose was given in fractional doses at intervals of eight hours for the first month and of six hours for the second month. Immediate and late results were satisfactory. The good results persist, after a period of two to seven months after discontinuation of the treatment.

**Poliomyelitis.** — Romero and Armijo studied the clinical records of 515 children with poliomyelitis who had been observed in different children's hospitals of Santiago since 1920. The disease was previously sporadic. Since 1935 it has been epidemic. The acuteness of the disease and the number of cases increase every year. The seasonal and age distribution are similar to classical descriptions. Few cases with transitory paralysis or paresis were observed. The bulbar type was rare. In spite of the low mortality, it is believed that in future there may be more serious forms with a tendency for the disease to occur in adults.

## Strasbourg Médical

**108:**197-208 (June 25) 1948

*Treatment of Leukemias with Urethane. Results Obtained at Medical Clinic A. A. Fitzenkam and R. Voegtlin.—p. 197.
Actual Orientation in Neuropsychiatry of Children. M. Mathis.—p. 201.
Precocious Anti-Rhesus Immunization in Course of Pregnancy. Pathogenic Considerations. R. Keller, R. Waitz, J. Fourcade and L. Grimault.—p. 203.

**Urethane in Leukemias.**—Fitzenkam and Voegtlin treated 9 patients, 7 men and 2 women between the ages of 15 and 66 years, 4 with chronic lymphoid leukemia, 2 with myeloid leukemia and 3 with subacute and acute leukoblastosis, by administration of 3 Gm. of urethane daily for seven days to two and one half months. Results showed that acute or subacute leukoblastosis do not offer any indication for treatment with urethane. Death occurred in 2 of the authors' cases. Chronic myeloid leukemia may be considered as a primary indication for treatment with urethane, not only because of the reduced leukocytosis but also because of the general improvement, the definitely reduced splenomegaly and the normalization of the leukocytic formula. In 2 of the patients with chronic lymphoid anemia the leukocyte rate was reduced; in certain of these cases urethane may control the proliferation of leukocyte-forming tissue or it may prevent the passage of pathologic elements into the circulating blood. In 3 cases with or without a drop in the leukocyte count, 1 of which was fatal, the adenopathy did not subside or showed only little improvement. In 1 case it was definitely increased and in 1 the signs of pyramidal irritation remained unchanged. Urethane should be given a trial in early cases of lymphoid anemia in addition to roentgen therapy, while in advanced cases only roentgen therapy combined with blood transfusions should be practiced. In cases in which roentgen treatment proved effective, urethane may be administered between the irradiation series, and may be useful in preventing recurrences. Nausea was associated frequently with treatment with urethane, but the accident that is to be dreaded most is the blocking of the normal hemopoietic system.

# Book Notices

**Diseases of the Ear, Nose and Throat.** By William Wallace Morrison, M.D., Professor of Otolaryngology and Attending Otolaryngologist, New York Polyclinic Medical School and Hospital, New York. [New edition.] Cloth. Price, $8.50. Pp. 772, with 359 illustrations. Appleton-Century-Crofts, Inc., 35 West 32nd St., New York 1, 1948.

Morrison's book was originally published under a different title and has now been reissued in a revised edition. In forty-four chapters the author has succeeded in incorporating much of the up-to-date material in otolaryngology. Considerable literature is represented. Although he states in his foreword that the book is intended for the undergraduate student and general practitioner, he has included rather advanced material that would not be considered applicable for this group. For example, much space is devoted to the description of the fenestration operation for otosclerosis and other advanced surgical procedures that certainly would not be carried out by a non-specialist physician. The introductory chapters pertaining to history taking are of utmost convenience to the general practitioner, providing adequate material for his diagnosis.

While one can feel that the author's own line drawings involved considerable work, there is a question whether these would be acceptable from the standpoint of what is considered valuable in modern medical illustration, especially when such outstanding artists are available. The photomicrographs, for example, surely would be much enhanced by the use of originals, and the anatomic illustrations, although duplicated from standard drawings, lack authenticity in correctness.

A number of therapeutic considerations still remain to be brought up to date. The most recent material on the employment of antibiotics in otolaryngology is included. The author includes a 10 page formulary of his prescriptions. There is also an excellent symptom index which surely will be advantageous to the reader. The organization of chapter material presented from an etiologic to a treatment point of view is good, although the important phase of differential diagnosis is somewhat deficient.

**Management in Obstetrics.** By Andrew M. Claye, M.D., F.R.C.S., F.R.C.O.G., Professor of Obstetrics and Gynæcology, University of Leeds, Leeds. Oxford Medical Publications. Fabrikoid. Price, $3.75. Pp. 186, with 17 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E.C. 4, 1948.

This small book deals only with management of obstetrics, as indicated in the title. At the beginning of most of the thirty-six chapters there are quotations, mostly from Shakespeare, which show that the author has an excellent sense of humor. For example, at the head of the chapter "Abortion" is the quotation, "Like ships that sailed for sunny isles, but never came to shore"; in the chapter on "Twins" is "Double, double, Toil and Trouble"; in the chapter on "Breech in Pregnancy" is "Turn, hell-hound turn," and in the chapter on "Hydramnios" is "Too much of water hast thou, poor Ophelia."

The book contains much useful advice and many worth while recommendations. It is tersely written and usually dogmatic, but since the treatment prescribed is sound and practical this is no criticism. There are only seventeen illustrations, but, of course, this small book was intended to be used in conjunction with one of the large standard textbooks of obstetrics. For its limited field the book can be recommended highly.

**Bronchiogenic Carcinoma and Adenoma. With a Chapter on Mediastinal Tumors.** By B. M. Fried, M.D., Associate Attending Physician, Montefiore Hospital for Chronic Diseases, New York. Cloth. Price, $6. Pp. 306, with 118 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

This addition to the already voluminous literature on carcinoma of the lung is written by an author who has had a large clinical experience with the disease. It is written for the clinician. The material is presented in twelve chapters and three supplements interposed into the text. There are chapters on incidence, pathologic anatomy, histogenesis and classification, alveolar cell cancer and adenomatosis of the lungs, etiology, metastases, clinical manifestations, tumors of the superior pulmonary sulcus, laboratory methods of diagnosis, treatment, bronchiogenic adenoma, mediastinal tumors, and others.

Despite this imposing array of titles, the subject of cancer of the lung and mediastinal tumors is not completely covered. There are many omissions. On the other hand, there is a long chapter on hypertrophic pulmonary osteoarthropathy, and many digressions are made into interesting but nonessential subjects. Case reports are used to illustrate many points.

Probably no other major form of cancer has become surrounded by so many points of controversy as has carcinoma of the lung. The author expresses definite views on many of them. Thus, he accepts the theory of "chronic irritation" in etiology, and the basal cell of the bronchi in histogenesis ("primary carcinoma of the lungs is only bronchiogenic in origin"). He combines the concepts of alveolar cell carcinoma and adenomatosis (jaagsiekte), although on the basis of what evidence is not clear. In microscopic classification, oat cell and anaplastic tumors are regarded as varieties of squamous cells! He believes that an increase in cancer of the lung is more apparent than real.

This book, despite its good points, is recommended with reservations because of errors of fact, which are most numerous in the chapters on etiology and on pathologic anatomy, histogenesis and classification. It is not "well established that one of the factors leading to the development of a cancer is chronic inflammation (irritation) which causes degeneration of cells, followed by an excessive regeneration." It is also untrue that pulmonary tumor in mice . . . "never causes death of the animal," or that in influenza "the changes in the lungs caused by the supposed pathogen have never been fully described." The book could be greatly improved by additional editing.

**Arterial Hypertension.** By David Ayman, M.D., Instructor in Medicine, Tufts College Medical School, Boston. Edited by Henry A. Christian, A.M., M.D., LL.D., [Reprinted from Oxford Loose-Leaf Medicine with the same page numbers as in that work.] Cloth. Price, $2.50. Pp. 508 (173)-508 (265), with 9 illustrations. Oxford University Press, 114 Fifth Ave., New York 11, 1948.

This book opens with a brief foreword by Henry Christian, in which he states, "Dr. Ayman has had an extensive experience with hypertensive patients, whom he has subjected to long continued, thorough, clinical study in the homes of the patients, in the out-patient clinic, and in the wards of a hospital, before, after and when undergoing various forms of treatment, including sympathectomy . . ." This evidence of the author's qualifications to write on the subject of arterial hypertension becomes more and more impressive as the book is read. Dr. Ayman is writing from first hand information, from personal observations of hypertensive patients under a variety of conditions, and he interprets the results of his studies in an unbiased, objective manner.

Although this work is largely the result of the author's careful studies of a large number of cases, treated in a variety of ways, he is thoroughly familiar with the vast literature on the subject and frequently refers to the work or opinions of others. The chief value of the book, however, is the wealth of personal observations, evidently carefully recorded, and presented in a clear, simple style.

This work on hypertension is conveniently divided into numerous subdivisions. After a brief introduction and history of the disease, the possible causation is considered with emphasis on the hereditary nature of the condition and the possible nervous and psychosomatic factors. Experimental hypertension is discussed, but the author does not consider hypertension in man and the experimental animal as related. He considers the etiology of human arterial hypertension as absolutely unknown.

The pathologic physiology and gross and microscopic pathologic changes are briefly discussed, as are the constitutional type and personality of the hypertensive patient.

An excellent description of the symptoms and evolution of hypertension from its earliest stages to the most severe malignant type is given. This portion of the book is particularly commended and can be read with profit by students and practitioners alike. The physical and roentgen findings and electrocardiographic changes are briefly but clearly covered.

Particularly important is the section on treatment of the various manifestations of hypertension and of the elevated blood pressure, the latter being correctly considered as only a part of the over-all picture of the disease called arterial hypertension.

It is unusual in a work of this type to consider separately the treatment of psychoneurotic, vasospastic and organic symptoms, but it seems much worth while.

The surgical treatment of hypertension by splanchnicectomy is fairly presented; contrary to the view held by many internists, this author, basing his opinion on close personal observation, considers that the operation has definite value.

The usual medical treatment, including the use of potassium thiocyanate, is of course included. A bibliography of 99 titles, all referred to in the body of the book, and a useful index complete the volume. It is definitely recommended as a clear, concise exposition of arterial hypertension and its treatment.

**Fundamentals of Immunology.** By William C. Boyd, Ph.D., Associate Professor of Biochemistry, Boston University School of Medicine, Boston. Second edition. Cloth. Price, $6. Pp. 503, with 50 illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1917.

This widely accepted standard treatise on immunology is highly recommended as collateral reading for all graduate students in the medical sciences and medical and veterinary students. Its wealth of basic material and comprehensive bibliographies make it a valuable reference work for the advanced student of immunology and the practicing physician.

The second edition retains all outstanding features of presentation and organization that characterized the original work. The two most notable improvements in its organization are the addition of excellent summaries at the end of each chapter and the elimination of passages in small type. Bibliographies have been brought more nearly up to date and provide a broad coverage of fundamental source material.

Much new material has not been added; however, much of the old material has been worked over and rewritten in the light of more recent experimental data. A thorough going discussion of the Rh antigen and all of its medical implications has been added. The methanol precipitation method of purifying bacterial toxins and the use of ultraviolet irradiation for inactivation of various virus vaccine preparations are discussed.

Detailed chapters on anaphylaxis and allergy, allergy and immunity, practical use of immunity, and laboratory and clinical technic are included.

***Minor Surgery.*** *By Frederick Christopher, B.S., M.D., F.A.C.S., Associate Professor of Surgery, Northwestern University Medical School, Chicago, Ill. Sixth edition. Cloth. Price, $12. Pp. 1058, with 937 illustrations. W. B. Saunders Co., W. Washington Sq., Philadelphia 5, 1948.*

The sixth edition does not vary greatly from previous editions except in an obviously successful effort to keep abreast with progress in surgical science. All the newest advances which have gained acceptance as useful technics are included. The number of references is enormous and direct quotations are employed with advantage. Numerous forms of therapy are cited. In the treatment of so-called minor surgical problems there are often many ardently advocated methods, whereas in the major surgical fields the advocated technics are fewer but the discussions are equally heated. This leads one to the conclusion that minor surgery is that performed by every clinical physician and surgeon, and major surgery is that performed only by specialists. A good definition!

**A Symposium on the Use of Isotopes in Biology and Medicine.** By Hans T. Clarke and others. [Addresses Delivered at an Institute Held at the University of Wisconsin from September 10 to September 13, 1947.] Cloth. Price, $5. Pp. 445, with illustrations. University of Wisconsin Press, Madison, Wisconsin, 1948.

This symposium is an authoritative collection of papers presented by men prominent in the field of radioisotopes in medicine and biology. Important uses of isotopes in biology and medicine are adequately covered in not too lengthy chapters. Use of isotopes as tracers in protein, fat, carbohydrate and mineral metabolism is discussed in some detail. The present status of radioiodine in the study of thyroid physiology and treatment of hyperthyroidism is well covered. The uses of radiophosphorus in the treatment of certain blood diseases, as well as the application of numerous other isotopes as diagnostic aids in health and disease, are presented.

Of great importance to the physician are the sections dealing with the production and availability of isotopes, the proper methods of handling and measuring them and the necessary safeguards against the health hazards in connection with their use.

Finally, there are papers discussing the international, political, and social aspects of atomic energy and its role in the future.

**Electroencephalographic Study of Neuropsychiatric Disorders: Covering *159 Cases of Epilepsy, 53 of Suspected Epilepsy, 122 of Nonepileptic* Abnormality and 101 Control Cases.** By Torsten S:son Frey. From the Swedish by Helen Frey. Acta psychiatrica et neurologica, Supplementum XLII. Paper. Pp. 172, with 19 illustrations. Stockholm, 1946.

**Investigations on the Basis of Rational Electrotherapy of Paretic Muscles.** By Svend Clemmesen and Erik Skinhøj. Acta psychiatrica et neurologica, Supplementum XLIII. Translated from the Danish by Axel Andersen. Paper. Pp. 53, with 19 illustrations. Ejnar Munksgaard, Nørregade 6, København, K, 1947

"Electroencephalographic Study of Neuropsychiatric Disorders" is a review of the literature of electroencephalography up to 1944 and a general discussion of technical difficulties in performing this diagnostic test. Types of electrode placements and difficulties inherent in the so-called indifferent electrode are discussed. The ear is considered a source of electrical activity from the nearby temporal lobe. Some of the artefacts that make interpretation of electroencephalograms difficult and quantitation of the procedure and its limitations are handled clearly.

In the author's series, over 20 per cent showed abnormal records. This is higher than in other series reported either in this country or abroad, and is probably explained by the method established to quantitate insignificant variations from normal. Handling of his clinical material makes dull reading. There is a plethora of tables and minutiae concerning all the data available. Positiveness about specific personality characteristic of patients with epileptic seizures is, of course, not accepted by the best neurologists and psychiatrists and his data in this regard are entirely inadequate.

Specialists in electroencephalography would find the volume of interest, but it is not recommended to neurologists or psychiatrists, because it contains far too much detailed material.

"Investigations on the Basis of Rational Electrotherapy of Paretic Muscles" actually contains three articles: (1) "On the Value of Electrotherapy in Treatment of Flaccid Paresis," (2) "On Choice of Form, Intensity and Duration of Impulse" and (3) "On Intensity Duration Curves (I/T Curves)."

In the first article there is an interesting discussion on electrotherapy in the treatment of paretic muscles, but it does not cover all the literature.

The authors give detailed wiring diagrams and descriptions of apparatus and data to show that the most effective type of electrical stimulation is the square wave of a duration of around 25 milleseconds, whereas round waves and pointed waves are not so effective. There is an important technical note on the ingenious method which the authors use in varying voltages mechanically by means of an arm on a potentiometer activated by movement of the muscles so that the myogram can be converted quantitatively to a recorded electric pulsation on the same screen, or bromide paper, as the stimulus current.

The third paper, contains well known data on strength duration curves. This confirms data already in the literature.

Both these books represent much effort on the part of these investigators during war years when equipment and funds were difficult to obtain. Criticism, therefore, should be tempered with an understanding of these handicaps. Both of these are worth having in a neurophysiologic laboratory for specialists in this technic.

**Peripheral Vascular Diseases: Diagnosis and Treatment.** By David W. Kramer, M.D., F.A.C.P., Associate Professor of Medicine, Jefferson Medical College, Philadelphia. Foreword by Edward L. Bortz, M.D. Cloth. Price, $8. Pp. 620, with 157 illustrations. F. A. Davis Co., 1914-16 Cherry St., Philadelphia 3, 1948.

This volume successfully conveys a practical approach to the problem of peripheral vascular disease. The author presents numerous illustrated histories to emphasize practical points. The discussion is excellent. General practitioners will find this an especially useful bridge to their approach to a neglected but large field of medical understanding.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## GIRLS' BASKETBALL

*To the Editor:*—Does playing basketball injure girls? Some physicians say that it is too strenuous. Should basketball be avoided during menstruation?

J. O. Helm, M.D., New Florence, Mo.

ANSWER.—Basketball can be played safely by girls if the following precautions are taken: (1) Examination by a physician to determine fitness for strenuous exercise, (2) use of girls' rules, which limit activities to zones on the court, (3) assurance that the contesting teams are reasonably well matched in age, size and training and (4) proper control and supervision.

Basketball with these precautions should not be more dangerous for the girl than for the boy. Though some girls can play basketball during menstrual periods without difficulty, many others will find it wise to omit such strenuous exercise for the first day or two of each menstrual period. This individual difference can be determined only by personal experience.

## ONYCHAUXIS

*To the Editor:*—A patient was seen with herpes zoster involving the sixth dorsal segment on the right. This was a minimal attack with little pain or discomfort. Her physical examination evolved no other abnormalities except for a condition of onychauxis involving all the nails of both hands and feet. There was pronounced hyperkeratinization of the nails and piling up in the typical irregular fashion. The basal metabolic rate was —18 per cent. She had taken thyroid previously with some benefit, but without effect on the condition of the nails. She disclosed that twice during pregnancies her nails gradually returned to normal and remained normal until two or three months after delivery. Then there was a gradual recurrence of the abnormal condition. Is there information available which might lead to a rational treatment of this condition?

Seth W. Ellis, M.D., Anderson, Ind.

ANSWER.—This case of onychauxis, like others of this type, is difficult to analyze completely for causation. The basal metabolic rate of — 18 per cent might point to a partial solution, although thyroid therapy has not materially helped. Dystrophies of the nails have been observed in cases of hypothyroidism, but the clinical picture is usually that of decrease of size, brittleness and longitudinal and transverse grooving. It is difficult to determine the cause of the decided improvement during and shortly after pregnancy. Naturally, an endocrine angle might be suspected, but nothing can be elucidated in a tangible way. Extraneous factors, as the application of nail polish, can be ruled out because of the concomitant involvement of the toe nails. In some of these cases the condition responds well to large doses of vitamins A and D. It takes six to eight weeks to effect improvement. At that time, thyroid medication can also be added if the improvement is slow.

## ALOPECIA AREATA

*To the Editor:*—A man of Greek extraction, aged 40 years, reported that he is losing hair in the beard regions and has been for the past two weeks. He has no other complaints. He has no loss of weight, and no apparent dermatologic condition at present. He has a history of syphilis some fifteen or twenty years ago, for which he received apparently adequate treatment. Physical examination reveals bilateral symmetric loss of beard on each side of the mandible for about 3½ to 4 inches (8.9 to 10.2 cm.) in area and getting larger. Blood sugar was essentially normal, as were the serologic reactions. An attempt to demonstrate fungous growth of the skin failed. What other possibilities exist? I have considered pituitary or adrenal syndromes as possibilities.

J. J. Stark, M.D., Belpre, Ohio.

ANSWER.—The patient apparently has alopecia areata affecting the beard only—a condition in which there is complete loss of hair in circumscribed areas without visible inflammation or scars. The cause of alopecia areata is unknown, though many cases give ample evidence to suggest a link between alopecia areata and the emotions. The prognosis should be guarded, though in most cases regrowth of hair does occur. The treatment is by stimulating measures, such as massage, ultraviolet rays or the application of strong medicaments, such as 10 per cent ammoniated mercury ointment. From time to time, treatment with roentgen rays is advocated, but if they are used, it must be with extreme caution by one skilled in the treatment of diseases of the skin with roentgen rays.

## DERMATITIS FROM RUBBER GLOVES

*To the Editor:*—Of two types of surgeons' gloves commonly used in hospitals —latex gloves and the cement type of gloves—the former is made from pure gum latex imported in liquid form, while the second type is made from high grade Para rubber from Brazil imported in the form of smoked sheets. A larger percentage of hospitals are using the cement type of glove rather than the latex glove, despite the fact that comparative tests show the latex glove to be superior in tensile strength, elongation and resistance to aging. The preference for the cement type glove appears based on the idea that latex produces a greater incidence of allergic reactions among surgeons and nurses. Our investigations of this subject have not revealed any reliable proof for this assumption. Do you know of any studies which have been made on the two types of gloves to show the relative sensitiveness of skin when in contact with them? We believe that hospitals could save money by purchasing latex gloves and feel that such a recommendation should be made provided that there is no scientific proof that a pure latex gum glove is more hazardous.

Hospital Bureau of Standards & Supplies, Inc., New York.

ANSWER.—Reports of studies on the incidence of dermatitis from latex gloves as compared with cement (dipped) gloves are not available. The problem of preventing dermatitis from rubber gloves is not always as simple as the substitution of latex gloves for dipped gloves, or vice versa.

Gloves may be made from natural rubber and natural rubber latex or from the synthetic rubbers and synthetic rubber latex. There are many types of synthetic rubbers differing widely in chemical composition. Buna S is a copolymer of styrene and butadiene. Buna N is a copolymer of styrene and acrylonitrile. Neoprene G.R.N. is polymerized chlorobutadiene, and there are several other types of synthetic rubbers. Dermatitis from synthetic rubbers is more frequent than from natural rubber.

Many accelerators, antioxidants, plasticizers and other chemicals are added to all rubbers to make them suitable for gloves, and they differ in chemical composition. They are the most frequent causes of dermatitis. Rubber goods are often cured or vulcanized by exposure to the vapors of sulfur monochloride instead of to heat, and the compounds continuously being formed on the surface of vapor-cured (acid-cured) rubber may cause dermatitis. There is no one cause of dermatitis from wearing rubber gloves.

For further discussion of the subject, you may refer to: Schwartz, L.; Tulipan, L., and Peck, S. M.: Occupational Diseases of the Skin, Philadelphia, Lea and Febiger, 1947, pp. 495-517, and Schwartz, L., and Pack, S. M.: Dermatitis from Wearing Apparel, J. A. M. A. **128**:1209-1217 (Aug. 25) 1945.

## IRREGULAR MENSES

*To the Editor:*—A 19 year old patient has never had regular periods. They vary from five to six weeks to three months. Her periods started at the age of 14 years. She is large for her age, and her parents are large also. The mother is fearful that there may be cause of underdevelopment of the female organs that might make it impossible for her to bear children. Should the condition be ignored as the girl is strong and healthy?

M.D., Nebraska.

ANSWER.—The patient deserves study from an endocrine point of view. She should have a pelvic examination to rule out pelvic pathologic conditions. This can frequently be done without one's disturbing the hymen by a one finger vaginal examination, a rectal examination and a rectovaginal examination. A narrow Pederson speculum gives adequate access to the cervix. A careful physical examination should be done with special reference to body figure, fat distribution, skin texture, presence of thyroid enlargement and breast size. Tests of basal metabolism and blood cholesterol should be done.

Possibly the drinking water is low in iodine; if that is so, sometimes patients need a little strong iodine solution to start with, and then the use of iodized table salt will give the thyroid gland adequate amounts of iodine for normal function. A basal body temperature chart, with daily morning temperature readings, and daily morning records of pulse rate records should be kept.

In the absence of any notable pathologic condition and even if the basal metabolic rate and cholesterol level are normal, one may safely give small amounts of thyroid, starting usually with ½ grain (0.065 Gm.) and increasing it gradually, with at least three to four weeks between increases in dosage, and making sure that the morning pulse rate does not run above 76 or 80 regularly. Often, with this pulse adequate protein and vitamin intake will regulate the cycle. Patients should be kept down to normal weight. Many of these patients have either anovulatory cycles or infrequent ovulations. A further check on ovulation can be made by suction biopsy of the endometrium. This is best done during the first hour or two of menstruation. Sex hormone therapy, in general, serves no useful purpose in these cases. In many of these cases the condition "straightens out" in later life, but in many it does not and it may be followed by or accompanied with sterility.

experiment?" I did not stop to point out the actual scientific impertinence of the question, but proceeded to answer it on the basis of its ethical and material implications. I replied, "There is no political and military leader under the sun who could order or otherwise compel me to perform an experiment contrary to my moral convictions." The attorney inquired, "So then you would be shot?" I replied, "Yes, and in so answering I feel certain that I speak for thousands of people who live in the United States."

### TWO CATEGORIES OF NAZI MEDICAL CRIMES

Elsewhere[2] I have pointed out that the medical crimes could be classified into two categories, namely, the nonexperimental and the experimental. In the same publication, I gave several examples of each, which need not be reiterated here.

*Nonexperimental Crimes; Mass Killings and Euthanasia.*—However, I should again point out that the mass killings—the gassing chambers—were related to the euthanasia edict secretly issued by Hitler in 1939. Paradoxically, German criminal law as late as 1945 held that euthanasia constituted murder and that "the law must take care not to shatter the confidence of the sick in the medical profession." Medical ethics pledges that physicians are conservators rather than destroyers of life. In my opinion medicine is doomed if it ever consents to take part or permits any member in good standing to take part in a program of euthanasia applied for socioeconomic purposes. If euthanasia is ever introduced for such purposes, medicine should have none of it. Medicine should let the persons responsible for introducing it do the killing. *Physicians are conservators, not destroyers, of life.*

*Crimes Experimental in Nature.*—Most but not all of the experimental crimes involved a search for the answer to a worthy medical question. They were criminal in that they were conducted on human subjects without their consent and in many instances without giving them as much consideration as is given experimental animals.

### ANALYSIS OF THE CAUSES OF THE NAZI MEDICAL CRIMES

As a medical scientist, I could not be exposed to these atrocities of a medical nature without trying to determine their causative background. There were three questions for which I believed an answer could be established by documentary evidence. I shall proceed to ask and answer these three questions and then consider a fourth question.

(*a*) *Why were the experimental laboratories established at the concentration camps under the Nazi-SS Division?* This was a natural question because the Luftwaffe, like our own Air Force, had its own experimental laboratories. The Wehrmacht, like our Army, had its experimental laboratories. Why then was an aviation laboratory established in the concentration camp at Dachau by the SS? The Wehrmacht had a typhus laboratory at Krakow. Why then was a typhus laboratory set up at Buchenwald concentration camp?

One reason was clearly stated in a letter written by Himmler. This letter stated in effect that the Nazi-SS physicians and scientists must have laboratories so that they could demonstrate to the German people and the world that they too could make discoveries, as well as the scientists of the universities, army and air force. This is definitely a political reason, and other evidence supporting this is in the Court records. Another reason given for establishing the experimental laboratories at the concentration camps was that results could be obtained more quickly and surely by doing the experiments on human subjects rather than on monkeys, dogs, cats and rabbits.

(*b*) *What sort of people worked in these Nazi-SS laboratories?* The documents clearly revealed that some persons—scientists and pseudoscientists—worked there for reasons of political preferment, others because they had a gun at their head, and a few because their scientific curiosity submerged their morals. Still others rationalized their behavior on the basis of the philosophy that the end justifies the means or that if euthanasia is right, as it has been so considered by some in England and the United States as well as in Germany, then it is right to take the life of political prisoners destined to die sooner or later.

(*c*) *Is there any wonder that nothing of scientific value came from these laboratories?* How can honest results come from such a dishonest situation? Because of the difficulties of medical research, it is not easy to get reliable results when all concerned are strictly honest. I shall cite only one illustration of the tragically dishonest behavior that went on in these concentration camp laboratories. This example occurred in the typhus laboratory at Buchenwald and was related by one of the witnesses. "Dr. Ding, being placed under pressure by the Hygienic Institute in Berlin, demanded that we produce large quantities of typhus vaccine for the fighting troops. From that moment, we produced systematically two types of vaccine. One type was perfectly harmless but had no value. This was produced in large quantities and sent to the front. A second type was produced in small quantities by the American method and was highly effective. It was used only for special cases, and we, too, who worked in block 50 were repeatedly vaccinated with the potent vaccine." Other examples of dishonesty are in the Court record.

A fourth question could not be answered by documentary evidence. Four factors to be mentioned were presumptively concerned. This question was: *What was the causative background of the experimental atrocities in which some 100 physicians were concerned?* Why in a number of cases were recent medical graduates directed to operate and develop surgical skill on prisoners who required no operation? I sought an answer to this question by discussions with German physicians, with prisoners, with German refugee physicians, with a Swedish physician and with American physicians who had received medical training in Germany. Several factors emerged from these discussions. The first factor which emerged was that the compulsory sickness insurance system of medical care after operating over a period of years led to a debased regard for the poor and underprivileged patient. Patients were too frequently treated as numbers rather than individual human beings with inalienable rights and dignity. A second factor was the ideology of the *Herrenvolk*, which morally is intimately related to a debased regard for the poor and underprivileged. A third factor was the practice of euthanasia, which when joined with the first two factors logically leads to the mass killing of the aged, the chronically ill, "useless eaters" and the politically undesirable. A fourth factor was frequently mentioned, namely, the welfare of the armed forces was the supreme good and anything which helped or might help the armed forces was right. This illustrates again the philosophy that the end justifies the means.

---

[2] Ivy, A. C.: Nazi War Crimes of a Medical Nature, Federation Bull. 33: 133, 1947.

### MOST OF GERMAN MEDICINE REMAINED ETHICAL

It should be emphasized that the larger portion of German medicine remained ethical. It is also important to know that legitimate medical investigation was conducted in Germany during the war and, further, that a small group of physicians protested when they learned that prisoners were being used like animals in experiments in the concentration camps. Himmler called these physicians "traitors" and asked to be provided with a list of these persons with "Christian medical ideals."

### WHAT HAPPENED TO ORGANIZED MEDICINE?

As might be expected, many German physicians did not know what was going on in the concentration camps during the war. The reason for this was evident. Soon after the Nazis assumed power they took over the control of the organized medical profession. This control gradually became more and more severe. It was not long before free scientific discussion and criticism was suppressed, and scientific medical meetings became infrequent and were poorly attended. Contrary to the precepts of medical ethics, a student had to be or have been a member of the Hitler Youth Movement. A medical graduate could not obtain an internship unless he was a party member. The important lesson to be learned from this is that a political ideology can insidiously take over a medical profession of high ideals and subvert some of the members of that profession so that they will take part in atrocities and place that profession in a position where it is unable to protest effectively.

### IMPORTANCE OF MEDICAL ETHICS

My experience at the Nürnberg Medical Trials emphasized the great practical and humanitarian importance of medical ethics. It caused me to realize that my medical education in that regard had been deficient and that medical education today is negligent in teaching the young physician the relation of the ethics of medicine to the economics of medicine. The instruction to the layman has been neglected even more. The layman cannot be expected to understand the fact that medical economics is based on medical ethics, if the young physician does not understand it. It is difficult for many laymen and some young physicians to understand why an attempt to introduce commodity economics into medical practice has led to conflicts and difficulties. More instruction regarding the meaning of medical ethics should be given to the medical student and the layman.

### THE CONTRIBUTIONS OF HIPPOCRATES

Though I had been in medicine for thirty years, I realized, for the first time at the Nürnberg Trials, the full meaning and importance of the contributions of Hippocrates and his school to medicine and human welfare.

Hippocrates contributed the scientific philosophy of medicine as we know it today when he taught that disease is due to material causes and not to evil spirits, witches or the wrath of gods. He contributed a technical philosophy when he taught that diligence, accuracy, thoroughness in observation and skill were essential for success in the practice of a science and art of medicine. He apparently realized that a scientific and technical philosophy of medicine could not survive through the ages unless it was associated with a sound moral philosophy. One cannot conceive of a sound society with medicine that does not have a sound moral philosophy.

### A MATERIALISTIC SCIENTIFIC AND TECHNOLOGIC PHILOSOPHY HAS NO SURVIVAL VALUE

Similarly, I believe that no nation can expect to survive on the basis of a materialistic scientific and technical philosophy alone. Fascism and national socialism failed because they were devoid of a sound moral philosophy. Marxian or materialistic communism is doomed to fail because it has no moral philosophy. These totalitarian forms of government place the welfare of the state above that of the individual. They fail to consider the historical fact that every form of totalitarian government has sooner or later succumbed. They fail to consider the biologic fact of the "primacy of the individual." They fail to consider that the rest of the world suspects, resents and will line up against the super-race, or the group that would rule the world for its own aggrandizement or the allpowerful nation that takes more than it gives. We must accept the premise that human beings are in a practical sense free agents. The ultimate goal in social welfare is the maximum development of the individual. It would seem self evident that everything of value in human society depends on the opportunity for the development accorded to the individual.

### THE INDIVIDUAL COMES FIRST IN MEDICAL ETHICS

Medicine or medical ethics concurs in placing the emphasis on the individual. Simply stated, medical ethics, or the Oath of Hippocrates, is the Golden Rule of the profession. It states how one physician would like to be treated by another physician and pledges that such ethical treatment should be extended to the patient. For twenty-two centuries, or since the formulation of the Oath of Hippocrates, the principal concern of medicine has been "the welfare of the patient." Of course, the prime social reason for the existence of the profession is "the service it can render to humanity" by maintaining health and postponing death. But this social purpose, except for certain aspects of preventive medicine, can be achieved only by dealing with the individual. The physician is obviously the only person who can be morally and legally responsible to his patient, and, conversely, the patient is morally and legally responsible to his physician. This physician-patient relationship can freely operate only where the free choice of a physician or clinic by the patient, and the free choice of a patient by the physician, except in an emergency, are unrestricted. Obviously a third party or agency cannot assume this confidential personal relationship and the moral responsibility involved.

### IF MEDICAL ETHICS ARE ABROGATED CAN MEDICINE SURVIVE?

Though a reverence for the life of the individual is the basic aspect, the doctor-patient relationship and the free choice of a physician represent the realistic aspects of the moral philosophy of medicine. It is important to realize that these and a few other aspects of the ethics of medicine have survived for twenty-two centuries, and the chief reason they have survived is the enduring realistic fact "that a sick person requires the care of a specially trained person and that the sick person must trust and have a reason to trust the specially trained person." It follows presumptively that as long as this personal relationship exists in the care of the sick, the same basic medical ethics are essential for the survival of the profession and the welfare of the sick.

Therefore, I believe that it is the duty of every physician to oppose any plan of medical care which would immediately or ultimately jeopardize the doctor-patient relationship and the patient's free choice of a physician or clinic, or lead to competition between physicians on the basis of fees rather than the quality of service or remove the control of the practice of medicine from physicians who are subject to the ethical code of medicine.

### STATE MEDICINE AND COMPULSORY SICKNESS INSURANCE INTRODUCE DETERIORATING EVILS

Most systems of state medicine and compulsory sickness insurance introduce such deteriorating evils. It has been argued that these forms of medical practice lead ultimately to a deterioration in the morally responsible attitude of some physicians. This argument has not been seriously accepted by many laymen and by some physicians. These persons know that, at the present time under the existing medical code, the great majority of physicians are keenly aware of their moral as well as legal responsibility to their patients. They know that the physician is theoretically pledged to aid any sick or injured person, friend or foe, rich or poor, powerful or weak. They know that the ethics of the profession teach that no matter what *system the physician is compelled to work under*, the physician should do his best for the patient. In fact, the American Medical Association has said, in speaking against the evils of state medicine and compulsory sickness insurance, "If these (evil) things are embodied in legislation and become a part of the environment within which the profession must practice, there is scarcely any alternative except to continue to give the best service possible under such handicaps."[3]

But can these highly laudable ideals be maintained under a code of compulsory health insurance at the level at which they are maintained under the present medical code and practice systems? The evidence with which I am acquainted indicates that the answer to that question is NO.

I am convinced that the system of state medicine in Germany was in part the cause of the deterioration in the quality of German medicine and of the medical atrocities. But, as I indicated previously, state medicine was not solely concerned; there was also a general decline in moral and religious values, which probably precipitated a multitude of atrocities. How long medical ethics must be abrogated to lead to a significant deterioration of medical care is uncertain. Likewise, how long churches and other institutions standing for morality must be removed from a population to produce a Sodom and Gomorrah is also uncertain. It took the Russian Communists only about fifteen years to learn that unrestricted abortion was not good for Soviet Russia. Hippocrates knew that twenty-two centuries ago. Some who have visited Russia know that one can obtain "extra" medical and dental service for a "fee on the side."

These points are made to show again that there is more to medical care than scientific knowledge and skill. They also show that the environment in which the physician is raised and trained, as might be expected, has an effect on him and his activities regardless of the ethics of medicine. Scientific knowledge and skill in medicine have to be cultivated, nurtured and protected. Likewise, the moral and honorable aspects of medicine have to be cultivated, nurtured and protected. This is obviously accomplished more easily and successfully in a favorable than an unfavorable environment.

No group of citizens is more aware or can possibly be more aware of these facts than the men of experience and wisdom in the medical profession. The law can punish gross moral irresponsibility, but this is not enough. Who can cultivate, nurture and protect all of the aspects of medical care better than the medical profession? The profession is morally responsible for providing the public with the best possible medical care. The profession would be derelict in its duty if it yielded without vehement protest a major part of this responsibility to any other group, especially to one whose business and political ethics might be substituted for medical ethics.

Why should any government desire to change a system of medical practice against the recommendations of the large majority of the leaders of one of its most noble and conscientious professions? Medicine naturally resents any implication of its unwillingness to act for the best of the health welfare of the people. Medicine has cooperated and will continue to cooperate to solve health problems. But, because of its scientific training, it must be convinced by facts that a real problem exists. Many lay persons have not been trained scientifically and obviously do not know the meaning of scientific proof. Also, if a problem does exist, the profession must be certain that the proposed remedy will do no harm. The medical student and the physician, from the time he enters medical school until he retires from practice, is repeatedly told that his treatment should do no harm. This precept, introduced by Hippocrates, is ingrained in the mind of the profession, and only a misguided public would want its physicians taught any other therapeutic principle. Hence, the profession is naturally very cautious that a treatment proposed as a cure for a deficiency in medical care will not do more harm than good. Medicine, however, being an experimental science, like any other science, is willing to experiment on a small scale. The experimentation must be necessary, however, because living things are involved, and unnecessary experimentation on living things is cruel and brutal.

### CONCLUSION

Regardless of the relatively excellent and steadily improving health of our people and the leadership which American medicine holds in world medicine, a better distribution of expensive diagnostic and therapeutic facilities is needed. This need, I believe, is recognized by the majority of physicians and is acutely felt by many of our citizens at the present time. In meeting these needs the great progress made under the present system of medical practice must not be forgotten or underestimated. Any new proposal must be carefully scrutinized lest it lead to a deterioration of medical care. The profession should oppose any false remedy or temporizing proposal. It is the moral duty of the profession to do so.

Any new plan for medical care or any significant change in the existing plan of medical care must by all tests preserve inviolate a reverence for the life of the individual, the physician-patient relationship, the patient's free choice of a physician or clinic, the free enterprise system and the vesting in the profession of a major part of the responsibility for medical service and its financial reward. Unless this is done, I am convinced that the American public will have sold their medical birthright for a mess of pottage.

---

## MEDICAL CARE OF THE NATION IN THE EVENT OF ANOTHER WAR

[*] JAMES C. SARGENT, M.D.
Milwaukee

It is now barely a year since the Council on National Emergency Medical Service outlined its concept of its task to the Board of Trustees and the House of Delegates and started out toward its accomplishment. The survey that the association had just completed through the magnificent work of the Bureau of Medical Economic Research at the behest of the Bortz committee had pointed up in bold relief some revealing facts concerning the excessive procurement of civilian doctors for military duty in the recent war and, particularly important, some astounding facts concerning their incomplete and at times inept utilization.

Through the insatiable demands of the military establishment the civilian population was stripped of its physicians to a degree that invited national disaster. There remained but one physician, in many instances well along in years and in some even recalled from retirement, to take care of 1,500 civilians presenting all the many ills that beset people from the cradle to the grave. Had an epidemic occurred of the proportions of that afflicting the nation in World War I or had we suffered civilian casualties of the nature and extent anticipated if war is to come again, such an unbridled withdrawal of doctors from the factories, from farming communities and from the many other war-essential civilian groups would have undermined national health and morale with just as severe consequences as if our armies had been defeated in the field.

The responsibility for this dangerous withdrawal of civilian physicians rested largely on two things. Until Procurement and Assignment got under way in the middle war years, there was no authority in government even mildly interested in the medical needs of the civil population, and by then the damage had been done. More responsible still was a table of organizational figures and a pattern of deployment and utilization of medical personnel within the military that dated back to World War I and in some respects even to Civil War days. But little of the technologic advances of modern medicine had taken root in the services and nothing whatever had developed in the way of interservice coordination in care of sick and wounded. No wonder, then, that utilization of personnel was at low ebb and requirements inordinately high. No wonder, either, that the doctors of America are left today with what borders on an abhorrence for any part of military medicine.

Confronted with this situation, the Council on National Emergency Medical Service saw at once that two major objectives must be attained before the medical and health aspects of a program of national defense ever could be adequately developed. Requirements of medical personnel by the military establishment must be brought in balance with civilian needs. And to accomplish this the medical departments of the armed forces must be reorganized to make the best possible use of the medical personnel available. The Council was composed of men who had served in uniform, men who were still a part of the military organization of our country, men naturally sympathetic to the problems of the services. I reiterate that simply to tell our Army and Navy friends again and again that the critical and questioning attitude which the Council has displayed has not come naturally. It has had to act on the genuine apprehension that doctors feel for the health and security of this nation as the clouds of war again gather. It knows the sharply limited medical man power with which the nation will have to get along, whatever comes. It knows that another war would bring quick and stark disaster if the mistakes in procurement and utilization of the last war are repeated.

To avoid this, two developments within the Defense Establishment seemed to the Council to be essential. First, there must be a permanent board of top flight civilian physicians working arm in arm with the Surgeons General at high enough level within the military establishment to supersede the uninformed and often arbitrary authority of command. In no other way can the important matter of health care of fighting personnel be kept under medical control. In no other way can the medical departments of the armed forces have the benefit of the highly developed technical knowledge of civilian medicine. In no other way can the doctors of the nation have a proper part in their own destiny as the threat of war drives them into uniform. To be and remain genuinely effective this joint board must be directly advisory to the head of the military establishment, the Secretary of Defense. Second, there must be a group of civilian physicians at top level within government having the responsibility of weighing the medical man power needs of industry, agriculture and the civilian population at large, of research, public health work and medical education against the requirements of the military establishment. Under the National Defense Act of 1947 such a Board would fall logically within the structure of the National Security Resources Board, whose duty it is to advise the President on the utilization of all of the war-important resources of the nation.

Accordingly, the Council advised the Board of Trustees and the House of Delegates of the urgent need of these two boards within the Defense Establishment. The recommendations were adopted at the June session of the House of Delegates, and the Association promptly urged their appointment upon the President, the Secretary of Defense and the Chairman of the National Security Resources Board. I am particularly happy to add, too, that both of these recommendations apparently enjoyed the wholehearted and active support of Surgeon General Bliss of the Army, Surgeon General Swanson of the Navy and Surgeon General Grow of the Air Force, as well as those high in their service.

Word has been received from the Office of the Secretary of Defense that on November 9 Mr. Forrestal officially approved the appointment of a joint civilian-military board advisory to him. Invitations have been extended and public announcement of this new board and its terms of reference awaits the final acceptance of all who have been invited to serve. With these two boards appointed to serve officially in the Defense Establishment one could hardly doubt, it seems to me, that the medical aspects of the defense plans of the nation will stay in proper balance and that in the future doctors in uniform will be kept busy and at tasks for which they are peculiarly trained.

---

[*] Presented before the Conference of State Medical Association Secretaries and Editors, St. Louis, Nov. 29, 1948.

Before leaving this scanning record of the early work of the Council may I pay tribute to the Secretary of Defense. With several others, and then only for a brief spell, it was my privilege to speak personally with Mr. Forrestal but once nearly a year ago. From time to time since then, however, his keen discernment has been apparent in matters that have been of interest to this Council, leaving each of us with the conviction that at least the medical aspects of national defense are in understanding and able hands. The profession might well wish and work for his retention during these years of threatening war.

That brings me up to date and to the heart of my assigned subject.

### A SPECIAL DRAFT FOR DOCTORS?

No one, it seems, has better than a gambler's guess as to whether war will again break upon us. War or no war, however, the country is embarking on a program of adequate military preparedness. A selective service act is already in force, and the Army, Navy and Air Force are presently in the throes of rapid expansion. That physicians are needed as part of that expansion is perfectly obvious, and many doctors are going into uniform in the months ahead. Make no mistake about that. This nation is in the habit of providing excellent care for its fighting men and we, of all people, would not have it otherwise. The fact that physicians always have volunteered for military duty and served in far, far greater proportionate numbers than those of any other walk of life is proof of that. Now once again, as the clouds of war thicken, the profession is faced with the moral and civic responsibility of seeing that there are doctors aplenty for the needs of the young manhood of America marching into service. If we are to be true to our heritage this movement must be voluntary, and it must be encouraged and guided by our great national association. Shame on the sons of Aesculapius if they ever bring this country to the necessity of a special draft. And double shame on this nation and its military men if, thoughtlessly and needlessly, they load its doctors with the onus of a special draft as a reward for the unusual sacrifices that they made in the last war.

Just how to avoid this impending debacle is a matter to which both the profession and the military must at once address themselves. It has implications that are far from reassuring to either party. The military might well recall the dissatisfaction and even disgust that were engendered in their medical reserves over the use that was made of them while in service and then contemplate the morale that would prevail in a medical corps drawn to that same sort of service and by an offensive and thoroughly discriminatory draft. Does the military desire that kind of a medical officer? On the other hand, the profession might well weigh the implications of a special draft of doctors—a draft not alone to treat soldiers and sailors but to supply medical care to several surprisingly large groups of nonmilitary personnel, veterans among them. Why not, then, another draft of doctors for service in our veterans hospitals? The Wagner-Murray-Dingel bills have been our nightmare for years, and here we stand on the very threshold of a form of Simon-pure federal medicine that would make monkeys out of the Falks and Cohens and Davises. There is no need to labor the point. Neither the military establishment nor the medical profession can let this thing happen. And I hasten to add that those high up in the medical departments of the three services are fully alert to the danger—far more so, I believe, than is our profession. You may disabuse your minds at once if you believe that drafting doctors is their choice.

### INCREASING THE FLOW OF MEDICAL VOLUNTEERS

Late as the hour is, it still is not too late to start a flow of medical volunteers into the services in numbers sufficient to fulfil all genuine needs. Our military friends have been critical of the apparent indifference of this Council and the Association to their estimated needs. They have grown skeptical of the possibility of meeting their requirements in any other way than by draft. They have underestimated, I am sure, our anxiety over their problem and have failed to properly credit our method of approach to its solution.

At long last there now is a committee of civilian physicians officially advisory to the National Security Resources Board. At long last a joint civilian-military medical board is being created within the military establishment advisory directly to the Secretary of Defense. The establishment of these two advisory groups long has been declared essential before the profession ever would dare to cast lot with the military establishment in any program of procurement of medical personnel. Now that they have been established the whole problem turns to ways and means of helping the armed forces obtain the doctors they need.

This help can take two forms. Of course, the organized profession can and must undertake an active campaign at once to inspire large numbers of needed enlistments. More of that later. Of far greater importance, simply because it goes to the very heart of the problem, the profession both in and out of uniform must cooperate in critical study of the drawbacks to military medical service and join in a vigorous and positive program to make military medicine more attractive to doctors. Gentlemen, there never will be a real solution, nor will the level of medical and health care within the services be of the best, until medicine has been elevated to a position of proper importance within the military establishment and then purged of those of its objectionable features that make it necessary almost to rope and hog-tie a doctor to get him into uniform and keep him there.

Completely outstripping everything else, the one blight that rests deadeningly on the medical departments of the armed forces is their utter subservience to command. No one wearing the caduceus on a uniform has escaped this withering feeling—no one from the Surgeons General to the most junior of the services. One could dwell all evening on the details of this depressing situation. One could dwell, too, on the grave danger that lies in a system in which final judgment in matters affecting the health of fighting personnel remains subject to the whims of an officer of the line. I wonder how many of you have seen Circular No. 342, Department of the Army, dated November 1948. In the very face of the threat of a war, the medical and health aspects of which never before have been equaled, this most recent reorganization of the Department of the Army actually forbids the medical department direct access to the Chief of Staff and places the Surgeon General among the Technical Staff and Services under the direction and control—yes, the direction and control—of the Director of Logistics. Now it may well be that in Civil War days when the medical department of the Army consisted of a few hastily acquired contract surgeons, medical service to the troops was simply a matter of logistics. But if modern medicine is to develop within the Defense Establishment as it most certainly must do in this age of atomic and biologic instruments of warfare, the position of the Surgeons General must be at top, not bottom, level. Last June the House of Delegates urged upon the President and Congress that the Surgeons General be elevated in rank and authority to the level of the Chiefs of Staff and the Chief of Naval Operations. Failing action, the same resolution will be introduced in this session and presumably again and again until the advice of American medicine is finally heeded.

There are many promising problems to challenge the thinking of a board of civilian physicians working arm in arm with the Surgeons General under the Secretary of Defense. I am sure there is none, however, that holds the same possibilities for great and lasting good that lie in seeking proper recognition of the importance of medicine in the armed forces of the future. Let us hope that that will be one of its major interests.

A well integrated program of career guidance within the services, offering opportunity for specialized training to certain properly selected medical personnel, is another most promising move toward improving the quality and the attractiveness of medical practice in the services. At the June meeting of the House of Delegates the Association went on record encouraging this forward looking development. It is regrettable to have to note, however, that its primary purpose of training specialists is becoming confused with personnel procurement and with a bureaucratic expansion of large military hospitals. The numbers and types of special trainees presently contemplated seem to go far beyond any reasonable needs of the regular services. And insufficient consideration seems to have been given to the possibilities that lie in carrying out this training program using civilian facilities already available and long experienced in that sort of work. In this connection it should be pointed out that young civilian physicians justly resent being asked to serve with the military and forego their own plans for special training just so that others within the services can become specialists. Particularly it should be pointed out that civilian physicians justly resent being asked to make the sacrifice of a tour of military duty on the basis of requirement figures that are inflated by a greatly expanded patient load made up of veterans, dependents and other nonmilitary personnel accepted in military hospitals to provide clinical material for their special training programs. This newly conceived special training program of the services is another important matter to be studied out carefully at the level of the Secretary of Defense between the Surgeons General and the leaders of civilian medicine. The program is much too worthy and much too essential to the future of military medicine to be placed in jeopardy by lopsided planning.

There are a number of other major matters that this joint board must interest itself in to improve the efficiency of the medical departments. Far, far better interservice coordination in the use of medical personnel and facilities can be attained. The Surgeons General working on the Hawley board have made a substantial beginning, but there is much yet that must be done. Genuine accomplishment along this line would reduce notably personnel requirements, improve materially the caliber of health care and enhance immensely the attractiveness of a medical career in all branches of service. Rank and pay commensurate with talent rather than with age in grade would do more to attract able young men to the services than most any other single thing. The American Medical Association lent substantial aid in the last Congress to secure an over-all increase of $100 a month in pay to medical officers, but much more must be done along this line to attract doctors to a career in the services. At least in times of peace, there must be more security of station and duty. And there are many other ways in which the effectiveness and the attractiveness of medical service within military can be improved to help meet the serious procurement problem facing the medical departments.

While there now seems great promise that many of these long needed changes are to be given fair consideration, they cannot be accomplished overnight. Meanwhile the nation is confronted with the threat of war, and its armed forces are faced with a serious problem in medical officer procurement, a problem that cannot await the careful and necessarily slow accomplishment of these important changes. The services have a genuine and urgent need for doctors and the American Medical Association and all of the state medical associations represented here today have a real responsibility in the matter. Of course, we shall remain critical of wastage of medical talent in uniform and we shall continue to protect the interests of the civilian population by questioning unreasonable requirements of doctors for the services. But America has determined on a program of immediate military expansion to meet the threat of a war. This very minute the flower of its youth is marching to battle stations with who knows what before it. There never was and there must never be a time when those of our profession remain unresponsive to the needs of men who are ordered to fight and die for our country. We have got, today, to face the fact that some of us again must leave home and practice and march wherever and through whatever those of the military must go.

I think I need not tell you that the Council on National Emergency Medical Service, the Trustees and Officers of our Association have been extremely busy for a year now acting on the determination of the profession to have a responsible part in the medical affairs of the military establishment. There are high ranking service men in this room who can testify to that. Indeed, the record itself tells the story. The Congress last spring refused to give the military establishment the unbridled authority over the profession that it sought. Several months ago a group of able physicians was appointed to the task of advising the President through the National Security Resources Board as to the over-all medical needs of the nation. And now civilian medicine has been officially established on equal footing with the Surgeons General and advisory directly to the Secretary of Defense on medical matters within the Military Establishment. Those are the major objectives that American medicine set out to accomplish as the mistakes of the last war became clearly evident. They are recited here so that doctors and public alike may have assurance that a proper and much needed liaison has been established between profession and government; that the medical departments of the Army, Navy and Air Forces are to be less wasteful of medical talent, more efficient and more attractive to doctors and, finally, that a proper balance is to be struck between civilian and military needs if a war is to come again.

There is every promise that the present requirement figures will be materially reduced in the coming months through the activities of these two advisory boards. At the same time it is perfectly evident that the steady increase in troop strength under selective service and the steady loss of A.S.T.P. and V-12 doctors who are terminating their tour of obligated duty will combine to create a shortage that soon will become genuine and intolerable. The point will be made clear by stating that the Army alone will lose 2,150 of its present medical officers the first eight months of next year and all of that in the face of a steadily expanding troop strength. Under these circumstances, I should dislike very much the task of appearing again before the Armed Services Committees of Congress placing the American Medical Association in opposition to a special draft of physicians if voluntary enlistments continue at their present snail's pace. On the other hand I firmly believe that if a respectable flow of volunteers can be developed in the meantime, special medical draft legislation will never reach the coming Congress.

To those of you of our state associations and to the doctors in your state whom you represent, the choice is yours. It takes no prophet to sense the alternatives. Either our organizations set their strong backs to the wheel or we will be yanked out of our rut by the heavy machinery of government. Either the young men of our profession—those who escaped service in the recent war and especially those who were favored by deferment to finish their education—will awaken at once to a civic duty to which they are morally bound or they will bring the ignominy of compelled service upon themselves and their profession.

Which shall it be?

# PHYSICIANS IN AN ATOMIC WAR

LEON O. JACOBSON, M.D.
Chicago
R. S. STONE, M.D.
San Francisco
and
J. GARROTT ALLEN, M.D.
Chicago

With the explosion of the first atomic bomb in New Mexico and thus the demonstration that the chain reaction is practical as a weapon of war, physicians and biologic scientists generally became an integral part of the development. To the many well known causes of medical casualties encountered in war and peace, such as blast injuries, penetrating wounds and thermal injuries, was added another—that of radiation injury.

Both the preclinical and clinical scientists are rapidly becoming acquainted with the biologic effects of radiations because (1) new types of penetrating radiations for therapy of cancer are being developed, radioisotopes are being more generally used for therapeutic and diagnostic purposes; both are being used as tools of fundamental research; and (2) the potential danger of actual atomic warfare makes knowledge of the biologic effects of radiations and methods of treatment an essential part of a physician's training. As a result, courses are being offered by universities, the Navy and the Atomic Energy Commission installations in order to make this knowledge more generally available.

Recently a series of stories appeared in the newspapers throughout the country on the picture which would obtain if atomic bombs were dropped on such cities as Chicago and New York. These stories were released at the time that a committee of medical experts met in Chicago to discuss preparedness for the eventuality of an atomic war.

The experiences gained at Hiroshima and Nagasaki have established certain facts which permit the formulation of certain broad principles to be followed if large cities are bombed. In the first place, it can be assumed, for the purposes of this discussion, that the amount of induced radioactivity or contamination with radioactivity in the vicinity of an explosion of an atomic bomb will be negligible. Therefore, teams of medical workers, etc., can immediately enter the area. This essentially reduces the problem to the treatment of external irradiation injury, thermal burns, blast injuries, penetrating injuries—in combination or alone. It is also clear that at the present state of our knowledge a large fraction (let us assume one third) of the population of a bombed city will be killed outright or will die in days to weeks no matter how soon they are brought under medical care. Another third of the population will survive if medical care is quickly and adequately provided, and the remaining third have a fair chance of surviving without medical aid unless epidemics break out or unless disruption of transportation and other basic facilities make it impossible to provide food, water and shelter. These considerations have led some persons who have given thought to a possible atomic bomb attack to suggest that all large cities be organized and mobilized roughly in the following way:

1. Facilities should be constructed on the outskirts of all large cities to provide hospital care, facilities for examination of ambulatory casualties and emergency rations for large numbers of persons.

2. One should plan for well trained and strategically placed workers to police and evacuate casualties, and, in general, operate as the workers in bombed English cities did during World War II.

3. One should provide for persons to be on the scene who are capable of calculating the center of the bombed area and determining the radius from the center in which, from the medical point of view, evacuation is essentially useless, the perimeter of the area in which evacuation is worth while and the perimeter beyond which little immediate medical attention is necessary. Such calculations can be made by reading previously located radiation monitoring instruments, by observations of the immediate biologic effects on persons within the bombed areas and others. Obviously the degree of destruction in a given city will depend on how close to the center of population the bomb explodes, the altitude at which the bomb is detonated and the size of the bomb. It seems likely that future atomic bombs will be no smaller and in all probability will be larger than those used at Nagasaki and Hiroshima.

Assuming that the medical profession and the military and civilian population of cities are organized adequately from the standpoint of preventing chaos, are able to evacuate casualties, and facilities are available for the care of the casualties, how does one separate the persons who require immediate hospital care and who

---

Dr. Jacobson, formerly Associate Director of Health of "The Plu-
tonium Project" under the Manhattan District, is now in the Department
of Medicine, University of Chicago, and Argonne National Laboratory.
Dr. Stone, formerly Director of Health of "The Plutonium Project" under
the Manhattan District, is now chief of radiology, University of Cali-
fornia Hospital, San Francisco. Dr. Allen, formerly with "The Plu-
tonium Project" under the Manhattan District, is now in the Department
of surgery, University of Chicago, and the Argonne National Laboratory.

have a chance of survival from those who are beyond hope of survival even with the best care? If, in such an emergency state, as physicians we accept the calculations of the physicists, health physicists and other experts who presumably will be on the scene and arbitrarily accept no casualties from a certain determined area of the bombed city, then part of this problem at least would be answered for us. Even with such an arrangement in force, however, the number of persons seriously ill with thermal and radiation injuries would be staggering. In addition, we would have to cope in one way or another with a large group of persons who required only minor immediate treatment but who might later have serious complications of radiation injury.

Enough experience has already been had with thermal injuries to make a rapid selection of those who require hospital care. Thermal burns and radiation burns are much alike in appearance, and treatment is similar. The treatment of injury from massive doses of penetrating radiations to the whole body is not unlike the modern supportive treatment given for extensive thermal burns. Although exact or entirely reliable information is not available on the amount of total body irradiation human beings can stand, it is probably roughly as follows:

Fifty to 200 r would produce slight nausea, a transitory mild leukopenia and thrombopenia with complete recovery.

Two hundred to 400 r would produce a moderately severe leukopenia, thrombopenia, mild transitory anemia, severe nausea and vomiting and diarrhea, and moderate hemorrhagic manifestations. Death would occur in a relatively small percentage of these persons, whereas the majority would recover spontaneously with symptomatic treatment only.

Exposure to 400 to 600 r would produce a seriously ill person with anemia, leukopenia, thrombopenia, hemorrhagic manifestations of varying severity, severe nausea and vomiting and bloody diarrhea. Even with excellent supportive treatment, one might expect less than 50 per cent of the persons in this group to survive. With doses above 600 r, on the basis of present knowledge, only a relatively few persons would survive even with the best of medical care.

As has been said, persons with severe radiation injury would likely have severe thermal burns as well. The irradiation and thermal injuries might be roughly classified under local and systemic effects.

The local effects of thermal burns such as edema, erythema and blister formation would appear within the first few hours. If such severe skin manifestations were to appear in the first few hours and could be proved to have been induced by radiation, the prognosis would be hopeless. However, the separation of thermal and radiation burns within the first few hours after such a catastrophe would be difficult or impossible. Therefore, if no penetrating wounds complicate the clinical picture, the skin should be treated as one treats thermal burns. The erythema, edema and weeping of the skin occurring after lethal or semilethal doses of penetrating radiation differ from thermal burns in that they may not appear for a week or more and then become progressively worse. Such systemic effects as those resulting from the loss of plasma, the depression of hemopoiesis, and infection are common to both. Therefore, the liberal transfusion of plasma is indicated from the outset of treatment. In severe cases at least 1 liter of plasma would probably be given daily. Daily whole blood transfusions will also be necessary to combat anemia; antibiotics and the like are indicated to combat infection, which is probably inevitable in the face of severe leukopenia secondary to destruction of bone marrow and lymphatic tissue. No specific treatment is presently known to combat radiation-induced leukopenia. Blood transfusions will, to some extent, help to combat serious hemorrhage. The use of specific antiheparin substances such as toluidine blue or protamine sulfate may be indicated. Because of the severe gastrointestinal inflammation and edema, the ability of such patients to take oral nourishment is minimal. As a result, practically all nourishment must be given parenterally. Sedation is also of great importance. One feature of radiation burns which differs from thermal injury is the fact that in radiation burns pain may be severe and persists for days. The use of morphine, codeine and other sedatives is therefore essential. There are many other phases of treatment which might be considered, but this brief account at least indicates the enormity of the medical problem involved in atomic warfare.

### RESEARCH WORK ON RADIATION INJURY

Not only is the research now being carried on in physics and chemistry on atomic energy being directed toward military application, but much effort is being expended to create peacetime applications such as heat and power. The research directed toward the medical and biologic effects of radiation has also been given great emphasis. Actually, this subject has received attention from the medical point of view since the pioneer work of Heineke in 1903.

The blood-forming tissue appears to be the most sensitive to radiation of any organ or organ system in the body. The penetrating radiations of significance from the standpoint of whole or partial body radiation from an external source are gamma rays, roentgen rays and fast neutrons. Qualitatively the biologic effects of these radiations are comparable. A dose of roentgen rays or fast neutrons or gamma rays given to the whole body which kills half of the exposed animals ($LD_{50}$) will, for example, produce a comparable degree of destruction of the hemopoietic system. The radiation sensitivity in the main cellular constituents of the blood may be listed as follows in terms of increasing sensitivity: erythrocyte, plasma cell, megakaryocyte, granulocyte, orthochromatic erythroblast and lymphocyte.

Some of the more recent work on the biologic effects of radiation which has already proved to be of some practical clinical value concerns a radiation-induced blood coagulation abnormality as reported by Allen and Jacobson.[1] Massive doses of radiation produce a prolonged clotting time (Lee White), and in some instances the blood may actually remain incoagulable for a period of twenty-four hours or more. This anticoagulant is probably heparin or a heparin-like substance, since it is reversible in vivo and in vitro by the administration of toluidine blue, protamine sulfate and other antiheparin substances. This defect appears in some animals even before platelets have been significantly reduced and in the presence of normal prothrombin, calcium and fibrinogen values. The value of these antiheparin substances in combating radiation-induced hemorrhage has already been demonstrated clinically.

---

[1] Allen, J. G., and Jacobson, L. O.: Hyperheparinemia: Cause of the Hemorrhagic Syndrome Associated with Total Body Exposure to Ionizing Radiation, Science **105**: 388 (April 11) 1947.

Another investigation in rabbits directed toward a practical approach to radiation injury was recently reported by Jacobson and others.[2] It was found that erythropoietic tissue in the bone marrow and spleen is definitely protected significantly from radiation injury if stimulated to massive production prior to irradiation. In these experiments erythropoiesis was stimulated by administration of phenylhydrazine or venisection.

These brief statements on research in progress are only intended to indicate that research work of a fundamental and practical nature is under way. The Atomic Energy Commission especially is subsidizing and stimulating work in this field. The medical applications of radiations and radioisotopes in diagnosis and therapy are receiving considerable attention. At this time only a relatively small number of the radioisotopes are practical and may be listed as follows:

Radiophosphorus ($P^{32}$): Oral or intravenous administration in the treatment of lymphomas, leukemias, polycythemia rubra vera and carcinoma mestastatic from cancer of the breast.

Radiogold ($Au^{198}$) and the Radiomanganese ($Mn^{54}$): Used in colloidal form in treatment especially of leukemias.

Radioarsenic ($As^{76}$): Used in the treatment of lymphomas and leukemias.

Radiosodium ($Na^{24}$): Used in the treatment of lymphomas and leukemias particularly and in diagnosis of vascular changes in the extremities.

Radioiodine ($I^{131}$): Used in the treatment of hyperthyroidism and carcinoma of the thyroid; of some value in tracer amounts in determining the functional state of the thyroid gland.

In all the discussion up to this point, no mention has been made of the possibility of using large quantities of radioactive materials in atomic warfare. A discussion of this would in itself require a review of our knowledge regarding the biologic effects of all the radioelements formed in the fission reaction. These elements number about thirty and are largely composed of radioelements which localize in bone. The fear that large quantities of radioactive isotopes might be dropped on large cities, in water reservoirs and the like is as frightening as the thought of bacteriologic warfare. Whole cities could be made uninhabitable and water supplies could be hopelessly contaminated by spreading radioactive isotopes by airplane. Depending on the concentration of isotopes dropped under such circumstances, we would be dealing medically with externally originating radiation to the whole body and to radioactive elements deposited within the body through inhalation, ingestion and the like.

It is interesting that the mammalian hemopoietic system has some measure of defense against radioisotopes which localize in bone.[3] For example, radiostrontium, which is physiologically interchangeable with calcium, is largely deposited in the skeleton when administered to the experimental animal. Although deposition in bone is general, the greatest concentration of the isotope invariably occurs in areas of active bone growth. An intraperitoneal injection of this isotope as the chloride in a dose of 2.0 microcuries per gram produces persistent leukopenia but no anemia of significance in the peripheral blood of young mice. The same dose produces both leukopenia and anemia in splenectomized mice. Hemopoiesis is markedly depleted in the bone marrow of all animals given such injections of radiostrontium. The metaphysial and epiphysial regions of the long bones are largely, if not completely, replaced by fibrous tissue. Extramedullary erythrocytopoiesis and megakaryocytopoiesis are greatly increased in the spleen by three days after injection of strontium 89 as is true of other intervals studied through more than one hundred and seventy-five days. Splenic lymphopoiesis, on the other hand, is reduced by three days, and recovery is not complete by ninety days. Myelocytopoiesis increases more slowly in the spleens of the animals given injections of strontium 89 over the period of observation. Extramedullary hemopoiesis is not remarkable in other tissues. The rapid development and persistence of extramedullary erythropoiesis in the spleen prevent anemia in mice given strontium 89 intraperitoneally in a dose of 2.0 microcuries per gram.

Until the present time no effective method has existed for removing these radioisotopes from the body once they have localized in bone. Attempts to utilize the same principles involved in removing lead from the body have been unsatisfactory. The dangers of these isotopes are largely confined to the eventual appearance of aplastic anemia, sarcomas of bone or lymphomas.

## SUMMARY AND CONCLUSIONS

In summary it is clear that at this particular moment, in spite of the fact that the atomic bomb was developed in this country and that great strides have already been made in terms of better understanding of the biologic effects of radiation, we would hardly be much better off to cope with an atomic bomb attack on one of our major cities than the Japanese were at Nagasaki. Leaders in medicine and radiobiology are giving attention to this problem and a plan and actual preparation for such an eventuality will probably evolve and be placed in operation. In the meantime, the government and universities are spending millions of dollars for research on methods of diagnosing, treating and preventing radiation injury. The physician must play a role in the investigation of these problems during this period of peace. That he will play a role in handling casualties in the event of an atomic war is inevitable.

---

**Renal Infarction.**—Foa described the gross and microscopic changes of a renal infarct caused by permanent ligation of a branch of the renal artery. At first the color is reddish gray, the infarct stands above the surface of the rest of the kidney and the tubular epithelium is swollen and cloudy and shows disintegration of its nuclei. The glomeruli and blood vessels, aside from edema and diapedesis of red cells, appear normal. There is a red zone surrounding the infarct, between it and the normal tissue, caused by tremendous engorgement of the capillaries. After 3 to 4 days the infarct has a gray color, the surface is level with the rest of the kidney, and the boundary zone is less red and wider. The tubular epithelium has lost its architecture and appears as a hyaline or granular mass. Many of the glomeruli show partial or complete necrosis and there are thrombi in the smaller arterioles. After 8 to 15 days the infarct has become smaller in all dimensions and is retracted from the surface of the kidney. There is a progressive contraction so that at 1½ to 2 months there may be found, at the site of the infarct, only an umbilication of the renal capsule, the infarct itself being represented by a yellow, contracted zone in the cortex. Occasionally there is left, in place of the infarct, a deep and irregular cyst or cavity which is covered with fibrous tissue and surrounded by exuberant parenchyma. At times the infarct may be reduced to a small calcified mass.—Regan, Francis C., and Crabtree, E. Granville, *The Journal of Urology*, June 1948.

# STATUS OF PERINEAL PROSTATECTOMY TODAY

DANIEL R. HIGBEE, M.D.
Denver

The purpose in presenting this subject is twofold: first, to present additional evidence on perineal prostatectomy as to its relative safety and good end results and, secondly, to endeavor to stimulate wider interest in the perineal surgical treatment of carcinoma of the prostate.

There are four available methods of relieving prostatic obstruction surgically: suprapubic, retropubic, transurethral resection and perineal prostatectomy. Each of these methods has certain advantages and disadvantages.

The suprapubic route is probably the easiest surgical method to master, requiring the shortest period of training to perform successfully, and uniformly gives good end results. Against it is the somewhat higher mortality than that of any other method, averaging in competent hands 4 to 6 per cent. Morbidity also is greater and hospital time longer. It should not be attempted in the treatment of fibrotic or calcareous obstructions or suspected cancer. In my own practice the procedure is limited to those patients with extremely large prostates (200 Gm. or over), those associated with large or inaccessible bladder tumors, large or multiple calculi, diverticula requiring excision and a few enlargements associated with atonic or neurogenic dysfunction. Mortality has averaged 5 per cent, morbidity 22 per cent; it is employed at the present time in approximately 3 per cent of cases.[1]

Retropubic prostatectomy, while newer and a little more difficult to perform, has been shown to be accompanied by less shock, slightly lower mortality, 1.75 to 6 per cent decreased morbidity (10 per cent), shorter hospital time and good end results provided certain precautions are taken. It is a relatively new operation, and statistics so far are somewhat limited. However, it does seem to violate one long established principle of prostatic surgery; namely, there is inadequate drainage with its associated problem of infection. There is also a relatively high incidence of stricture of the vesical neck unless a wedge of vesical neck tissue is removed at the time of operation. While it is suitable for the average adenomatous hyperplasia, it does not lend itself particularly to the treatment of very large adenomas, the small fibrous prostate and growths of suspected malignancy, though some early cancers are reported to have been removed successfully by this route.

Transurethral resection, boasting the lowest mortality (1 to 3 per cent), the lowest morbidity (8 per cent), shortest hospitalization and wide popularity with both physician and patient, would seem to be the best method, and is so considered by many able urologists. However, incomplete removal for various reasons, strictures and distortions of the urethra and vesical neck with resulting urinary frequency, occasional cases of incontinence and the lack of permanency of relief have somewhat dimmed its popularity. This method is admirably suited to bars, median lobes, vesical neck contractures, smaller prostates which protrude into the bladder, the average neurogenic bladder, to persons who are extremely poor risks and to persons with associated pathologic changes, such as accessible papillomas and calculi. In my own practice its use is now limited to these types of cases and to some younger patients in whom preservation of sexual function is of considerable importance. This amounts to approximately 37 per cent.

Perineal prostatectomy has not enjoyed the popularity of these three other procedures. In my opinion the underlying reasons are (1) lack of familiarity with the anatomy of the male perineum, (2) inadequate teaching, or the total absence of it, in many of the well organized medical centers and (3) the lack of courage on the part of the surgeon to follow through and master the approach in spite of having previously encountered a difficult case or one of the more serious complications.

Assuming that the surgeon has the average surgical skill and gentleness in handling tissue, he does need a good working knowledge of perineal anatomy, but, more than this, he must have adequate demonstration and teaching during his training and an opportunity of doing the operation often enough to do it skilfully.

Perineal prostatectomy is the one operation by which almost any pathologic change encountered can be adequately dealt with. In the words of Dr. Hugh Young[2]: "The great advantage of the operation is that it is performed under the complete visual control of the operator; that hemorrhage encountered is stopped, the enucleation is certain in its completeness; the verumontanum, ejaculatory ducts, the internal and external sphincters are protected, dependent drainage for urinary and inflammatory secretions is obtained, and the lowest mortality rate is secured." Newer methods, instruments and drugs have altered these truths very little.

The disadvantages are of course well known. Position during operation is unpleasant and may be associated with respiratory or cardiac embarrassment, though I have not seen either, using the Edwin Davis perineal elevator. Such complications as do develop may be unpleasant and difficult to overcome; namely, rectal injury, persistent perineal fistulas and incontinence.

This series of 350 consecutive cases is made up of 334 simple enucleations, 2 subtotal prostatectomies and 14 radical perineal operations which are analyzed separately. Prostates varied in size from 4 Gm. to 157 Gm. Of these 75 were recurrent adenomas or fibroadenomatous glands weighing less than 20 Gm. and 2 were calcareous glands, 1 removed by subtotal prostatectomy and 1 by leaving the capsule intact. These 77 cases were so treated in order to obtain good bladder tolerance and avoid stricture, which the operator did not feel he could assure by any other method. Later, 39 proved to have nocturia, grade 0 to 1, 4 nocturia, grade 2 to 3, and 3 nocturia, grade 3 or over. In 2 of the latter, examination showed prostatic tissue which had not been removed. These were treated by transurethral resection. In 1 case no cause could be determined. In the remaining cases no data are available. Twelve patients were operated on after abdominal sur-

gery complicated by acute urinary retention. Twenty-four had been admitted for hospitalization of medical illnesses. The 80 cardiac cases are discussed as a separate group. In other words, this series was not one of selected risks.

## THE GROUP OF 336 PATIENTS

### MORTALITY

In the first group of 336 patients 6 died, or 1.8 per cent; of these 2 were coronary deaths occurring twenty-four hours postoperatively, 2 were from large pulmonary emboli on the third and fourth postoperative days, 1 from septicemia twenty-four days postoperatively and 1 not related to the operation, from carcinoma of the cecum two months later.

### MORBIDITY

Complications developed in 39 cases, or 11 per cent; postoperative hemorrhage occurred in 13 cases, rectal injury in 11 (4 resulting in fistulas), pulmonary complications in 13, acute pyelonephritis in 2, cardiac disease in 4, toxic dermatitis in 2 and ligation of the left ureteral orifice requiring release in 1.

*Postoperative Hemorrhage.*—Postoperative hemorrhage requiring return to the operating room for evacuation of clots occurred in 13, usually on the day of operation, although in 3 it occurred after the sixth postoperative day. Ten of these complications were corrected transurethrally, 3 by reopening of the incision in order to replace the Bardex transurethral drainage. Of these patients, 6 were given blood transfusions, 2 of them twice. Blood loss, therefore, during and after surgical treatment has not been excessive, totaling 4 per cent of cases, with transfusion in less than 2 per cent.

*Rectal Injuries.*—In the 11 cases of rectal injuries, fistulas occurred in 4, or 1.2 per cent. In 7 of the 11 cases the perineal operation was abandoned; suprapubic enucleation was substituted in 2, and transurethral resection in 5. In 4 of the 7 cases healing was by primary intention; in 3 fecal fistulas developed which closed within a few weeks' time. In 2 of the 4 cases with rectal injury in which the perineal procedure was completed, the injury was discovered toward the end of the operation, and in 2 it developed five to seven days postoperatively. In 3 cases permanent healing required approximately three months, and thereafter there was no difficulty with either rectal or urinary function. The one remaining patient went elsewhere for consultation and could not be followed, though he was said to be alive and well three years after the operation.

*Pulmonary Complications.*—There were 13 cases with pulmonary complications, in 7 diagnosed as embolic pneumonia, in 4 as bronchopneumonia, in 1 as lobar and in 1 as diaphragmatic pleurisy. These complications, while not serious, prolonged hospitalization on an average of seven days.

The 2 patients in whom acute pyelonephritis developed approximately two weeks after surgery were operated on without preliminary catheter drainage, which was perhaps merely a coincidence.

*Cardiac Complications.*—There is a general impression that persons with cardiac disease stand prostatic surgery other than transurethral resection poorly, at least that the mortality will be considerably higher. The fact that there were 2 cardiac deaths and 4 other cardiac complications in this series does not bear out this belief so far as perineal surgery is concerned. Two deaths have been noted under the mortality statistics. One of these patients had a 37 Gm. prostate and complete heart block, with a pulse rate of 38 to 40, and died after a severe chill, forty-eight hours postoperatively. He had had no cardiac embarrassment until the chill occurred. The other death was of a man who had had repeated coronary attacks and transurethral resection three years previously with persistent frequency of urination and bladder irritability. Coronary occlusion occurred suddenly twenty-four hours postoperatively after a rather trying twenty-four hours of bladder discomfort, insufficiently relieved by sedatives.

Of the four patients who survived cardiac complications, coronary symptoms and signs developed in 3 and acute decompensation with pulmonary edema in 1 (associated with intravenous administration of dextrose). In only 1 of the 4 had the heart condition been considered of importance prior to operation, and all recovered completely. In 80 of the 336 cases cardiac risks were considered to be less than average prior to operation: persistent hypertension of 160 or over (54), advanced arteriosclerosis (3), evidence of previous coronary occlusion (4), cardiac decompensation (13), or one of the less frequent arrhythmias (auricular fibrillation 4, Stokes-Adams 1), heart block (2). Of this group in 13, or 17 per cent, some complication developed after surgery. Of the 54 cases with hypertension the highest pressure was 240 systolic and 140 diastolic; in 15 diastolic pressures of 100 or more were maintained before and after operation. In only 2 instances did an established hypertension subside permanently following operation. Of the 13 patients with histories of chronic myocarditis and signs of mild decompensation, after catheter drainage and digitalization, all but one progressed satisfactorily during the operation and convalescence, the exception being the patient in whom pulmonary edema developed.

On the basis of the findings outlined cardiac patients stand perineal surgery well, though there is probably less immediate risk if treatment is by transurethral resection.

*Fistulas.*—Persistent perineal fistula occurred in 1 case and was due to improper postoperative judgment and care. Use of the perianal incision elevating the levator ani anteriorly, followed by primary closure of the incision and transurethral drainage, seemed to have eliminated this complication, which statistics show formerly occurred in approximately 2 per cent of perineal operations.

*Incontinence.*—Fear of urinary incontinence is more widespread than is justified, for, if the mechanism of incontinence following perineal surgery cannot always be fully explained, the methods of avoiding it are nevertheless well agreed on: (1) strict following of lines of cleavage, especially in [illegible] the apical attachment of the rectourethralis; (2) [illegible] of unnecessary dissection and exposure, thereby interrupting as few nerve fibers as possible, and (3) gentleness and care in retraction, both laterally and anteriorly, in the region of the perineal body and external sphincter.

In this group of cases some degree of difficulty in holding urine immediately after starting to void was present in 17 per cent, remaining to some degree in 10 per cent at one month and in 3 per cent at the end of three months. The degree of incontinence varied from a few drops in 15 per cent to complete incontinence when standing in 5 patients. The latter were the slowest in regaining full urinary control. Four patients, approximately 1 per cent, had slight periodic urinary incontinence for nearly a year, and clothing of 2 patients, one a man of 83, was often slightly damp on visits to the office thereafter; the other patient, a man of 65 with chronic uremia and myocarditis, finally gained complete urinary control after one year.

### RESULTS IN ELDERLY GROUP

There was no mortality in the group of 25 patients 80 years or over, the oldest being 90. Preoperative catheter drainage averaged 7 to 9 days; postoperative time to voiding and healing was eleven days in 12 cases and up to twenty days for the remainder. Average hospital time was four weeks or less, though the longest period was forty-six days, in a patient who contracted pneumonia postoperatively. Prostates averaged 53 Gm. in weight, with two over 150 Gm.

There are some who believe that elderly men will not have good end results after perineal surgery. Of the 25 in this group, 12, or one half, had some degree of incontinence immediately, 2 being totally incontinent at first. However, all had normal urinary control within one to three months except 1 patient, aged 83, already mentioned. All developed good bladder tolerance with nocturia, grade 1 to 3, except one senile man who voided without knowing when this might occur. Five of the 25 had had previous transurethral resection.

### CONCLUSION

Conservative perineal prostatectomy can be carried out with low mortality, little blood loss, few complications and good end results at any age.

## CANCER OF PROSTATE

We have all treated patients having inoperable carcinoma of the prostate with, occasionally, surprisingly good results. Seven persons come to mind who have lived fairly comfortably between seven and nine years, in whom the diagnosis was proved, sometimes more than once, by transurethral excision. However, these cases are exceptional, and in my own practice the average length of life after initiation of palliative treatment is from three to five years.

When one considers that in 14 per cent of men over 45 cancer of the prostate develops,[3] that two decades of the various forms of radiation therapy have at best given palliative relief in less than 30 per cent of these cases, and that after nearly a decade of endocrine treatment and resection we are producing no proved cancer cures by these methods, we should give some thought to our responsibility to the public for our somewhat backward attitude in meeting this serious problem more decisively. The specialist cannot sit back and allow the man with a hard discreet area in his prostate, or for that matter one in whom there is some question of beginning extension beyond the capsule, to wait for obstructive urinary symptoms, pain or hemorrhage, to force him to initiate one or more of the established palliative measures.

Total perineal prostatectomy is not a particularly difficult procedure if one is doing other perineal surgery frequently, and surgical removal remains today the only means of producing a cure.

Funds are becoming increasingly available through cancer foundations. Educational programs, already well established, are beginning and will continue to bring more and more of these patients to us for early treatment following routine examinations. We must then be prepared to offer these persons a reasonable chance to be cured, and it is with this opportunity and obligation in mind that the following small group of cases is included.

### ERRORS IN DIAGNOSIS

Of the 14 patients subjected to radical perineal prostatectomy 2 proved to have no evidence of carcinoma on pathologic examination. Disconcerting as this is, both have good functional results. There were also 3 patients with carcinoma of the prostate treated by conservative perineal surgery followed by castration, in whom carcinoma had not previously been suspected. One patient, diabetic, lived comfortably for three years before dying of diabetes and "liver trouble." One remains in apparent good health after two years; the third died suddenly while making a radio address two and one-half months postoperatively.

### RADICAL PERINEAL PROSTATECTOMY WITH ORCHIDECTOMY

Of the 12 patients with proved carcinoma of the prostate treated by radical perineal prostatectomy 4 were castrated in conjunction with the operation as a result of suspected or proved malignant growth beyond the prostatic capsule. Of these, evidence of progression of the malignant growth by rectal examination is absent in 1 case at the end of three years, absent in 2 cases at the end of two years and in 1 case eighteen months after surgical treatment. The last patient mentioned showed carcinoma extending into the seminal vesicles. He had a good functional end result and was in good health without palpable evidence of cancer at a recent examination.

### RADICAL PERINEAL PROSTATECTOMY WITHOUT ORCHIDECTOMY

Of the 8 patients operated on by radical excision and partial removal of seminal vesicles but without castration, 5 are alive and show no evidence of recurrence (2 at the end of four years; 1, three years; 1, two years, and 1, one year following surgery). Of those not living 1 died of a pulmonary embolus on the fourth postoperative day, giving an immediate mortality of 12.5 per cent; 1 died one and one-half years postoperatively of pneumonia, postmortem examination showing no evidence of cancer, and 1 was a suicide two and one-half months postoperatively.

All patients were prepared by catheter drainage and 5 mg. diethylstilbestrol daily for ten to fourteen days. On rectal examination regression was evident or pronounced in 9 cases, sometimes sufficient to make the original diagnosis questionable. In 3 cases there was no evident change. Operability is therefore usually facilitated by preliminary treatment with diethylstilbestrol.

---

[3] Goodyear, W. E.: Perineal Prostatectomy: A Hope for Cancer Cure, J. M. A. Georgia 36: 425-427 (Nov.) 1947.

Following operation, convalescence was usually uneventful, though 1 patient was given a transfusion immediately after the operation. Nine healed by primary intention in twelve to twenty days, and the remainder on catheter drainage, the longest being thirty days. There was one rectal injury which healed primarily and, though 7 were totally or partially incontinent at first, all obtained good urinary control after a reasonable period of time.

### CONCLUSION

Radical excision should be attempted in all cases of cancer confined to the prostate gland and in those borderline cases which respond to diethylstilbestrol therapy. Biopsy may or may not be indicated when one is in doubt.

Patients encountered in whom complete removal is impossible because of extension or for other reasons apparently obtain as good palliative relief as those treated by other methods and, while a five to ten year period without recurrence will be necessary to establish the number of cures obtained, some of these patients will be cured of cancer. The number so treated and cured should increase steadily.

## EVALUATION OF TRANSURETHRAL PROSTATECTOMY

JOHN A. TAYLOR, M.D.
and
CHARLES H. PLACE, M.D.
New York

In a symposium on prostatectomy such as this, it is not our intention to defend the transurethral operation against any one of the other three methods, but rather to try to evaluate it as a surgical procedure and therapeutic agent in our hands, in contrast to enucleation by any one of the other methods. At St. Luke's Hospital, it has been our dictum that the method of approach rested with the surgeon and that he should be guided by his experience, so that when he operated he felt that he could offer the patient the best chance of cure. The suprapubic approach in our hands prior to 1932 left little to be desired, but the advent of transurethral resection offered a challenge.

The first transurethral resection was done in our hospital in June 1932. Resections were done at first with a great deal of trepidation because of the reported rates of morbidity and mortality in the hands of the early advocates of this method. In this manner, the many pitfalls were avoided. As our experience grew, it was felt with more than a modicum of modesty, three years later in 1935, when this present report begins, that the staff had attained a degree of proficiency comparable to that of the other groups of resectionists throughout the country. Early ambulation, which has since become so popular, the restoration of urinary function within twenty-four or forty-eight hours, the minimal surgical shock, allowing elderly poor risks literally to "breeze through" an operation, and the gratefulness of the patient himself led us to do more and more operations by this method. In 1935, 78 per cent of the prostatic operations were done by the transurethral method; in 1936, 82 per cent; in 1938, 88 per cent, and from 1939 through 1944 practically 100 per cent.

The observations in this paper are based on 1,066 cases handled by the various members of the Urologic Staff of St. Luke's Hospital between 1935 and 1945. It is believed that if one discusses the trouble which has been encountered in these cases a better evaluation is arrived at than if the good results were emphasized. In our series the average age was 66.55 years, the youngest being 44 and the oldest 96. There were 957 (89.8 per cent) cases of benign lesions and 109 (10.2 per cent) cases of carcinoma with retention.

### ANESTHESIA

During the first five years of this series, the transsacral block according to La Bat was used. It was definitely believed at that time that general anesthesia in patients, who as a rule were elderly, would add to the rates of postoperative morbidity and mortality. The science of anesthesiology has so advanced since then that this threat of trouble with general anesthesia had been reduced to a minimum. In 1940, one of us (J. A. T.),[1] in searching for a simpler procedure than the transsacral block, which had necessitated eleven punctures, utilized the lumbosacral subarachnoid tap, which required only one injection and which offered the patient less of an ordeal and the anesthetist a relatively simple procedure. This method has been used almost exclusively since then for resections.

### TWO OR MORE RESECTIONS ON FIRST ADMISSION

In 205 cases, or 19.3 per cent, another resection was necessary during the first hospital admission. It is believed that when one is using the transurethral method patients should not be allowed to leave the hospital unless they empty their bladders. Patients are told before the operation that one resection might not be adequate for complete restoration of function. The operator should have no qualms about doing a second or a third resection if the result is not entirely satisfactory. It has often been surprising, when patients have not emptied their bladders after transurethral resection how small an amount of tissue removed at the second operation will spell the difference between success and failure.

### IMMEDIATE POSTOPERATIVE HEMORRHAGE

There were 18 patients, or 1.7 per cent, who had postoperative hemorrhage, which necessitated their return to the operating room. Of these, 12 were controlled after the evacuation of clots and fulguration of the bleeding point. Six patients, or 0.56 per cent of all cases, required suprapubic operation for control of hemorrhage.

### DEATHS

The record of 5 deaths in this series justifies our application of the phrase "minimal procedure" to this operation. When one considers the age group, with concurrent cardiovascular changes, and the fact that many of these patients were operated on when they had stabilized high levels of urea, at figures that one would not consider favorable for open operation, then one must conclude that this method is far superior so far as fatalities are considered. One case to illustrate this point was of a Negro of 78 years, admitted

---

Read before the Section on Urology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

[1] Taylor, J. A.: Lumbosacral Subarachnoid Tap, J. Urol. 43: 561 (April) 1940.

in complete retention, in August 1947, with a history of repeated attempts at catheterization. On admission, he had a level of urea nitrogen of 49 mg., diabetes, cardiovascular disease, dilated aorta and a Bacillus coli infection of the blood stream. Treatment included blood transfusions, antibiotics and oxygen, and his condition was considered stabilized two months later. A transurethral resection was done under low spinal anesthesia, and 65 Gm. of tissue were removed. He voided well on the third postoperative day, and he emptied his bladder. He left the hospital for the convalescent home on his eleventh postoperative day. He was seen in the outpatient department on May 7, 1948. His only complaint was nocturia (two episodes nightly). He emptied his bladder, and a no. 26 sound was passed easily through the urethra. It seems to us that this patient could not have withstood open surgical treatment.

The first death was that of H. C., age 66, with cardiovascular disease, who had benign prostatic hypertrophy and a vesical calculus. At his first operation, on Aug. 12, 1937, a litholapaxy and a transurethral resection were performed, and he did well except for partial urinary retention. He was returned to the operating room on August 26; he had acute left ventricular failure with massive pulmonary edema and died on the table.

The second death was that of H. M., age 61, who was operated on Jan. 18, 1943. He had an uncontrollable hemorrhage on the operating table and was taken to the main operating room, where a suprapubic enucleation was performed. He died of hemorrhage on the table.

The third death was that of A. H., age 67, who was operated on Dec. 1, 1943. He went through the operation without any difficulty and progressed favorably until the Foley bag was to be removed on the second postoperative day. The bag would not deflate, and many urethral procedures were tried, with the subsequent development of a periurethral abscess and a Bacillus coli infection of the blood stream. He died three weeks postoperatively, with a cerebral hemorrhage. Since then, it has been learned that 2 cc. of chloroform injected into the bag when the bladder is filled with a neutralizing solution will dissolve the rubber cement that holds the bag to the catheter, and the bag can immediately be removed. This method was used in the only other case of failure of a bag to empty, with immediate success.

The fourth patient, J. J., age 66 years, was admitted in May 1936 with complete retention of urine, and was operated on May 11, 1936. Streptococcus hemolyticus septicemia developed, and the patient died of meningitis.

The fifth patient, G. D., age 58 years, was operated on Jan. 13, 1938. He had postoperative extravasation of urine, which suprapublic drainage failed to help, and he died of sepsis.

### STRICTURE

In this series, there were 16 cases, or 1.5 per cent, of stricture of the urethra following operation. The urethras have always been dilated gradually and carefully, with the idea of preventing any trauma, and the no. 24 resectoscope has been used in some of the smaller urethras. It is believed that at times when the resectoscope is passed, the end of the sheath will, unknown to the operator, cause trauma of the urethra. It is thought that this is one type of complication which could have been improved with the use of perineal section, a procedure which was not employed in this series.

### INCONTINENCE

There were 3 cases of incontinence. One patient, C. J., was 66 years of age in 1936, when he was operated on. He carried on his work thereafter with a philosophic attitude about his incontinence. He was retired and thoroughly enjoying life at 78—twelve years later.

The second patient was a man 63 years of age, who was operated on in December 1940 and at the time of writing was employed in the library of the hospital. He was examined on June 9, 1948—seven years after his operation. His urine was clear. He had complete incontinence and wore a clamp, and he was psychologically adjusted to his misfortune.

The third patient, 67 years old, operated on in 1939, was most unhappy about his condition.

### TIME BETWEEN RESECTIONS

It was toward the end of this series that the return of patients after several years of comfort, in whom symptoms of prostatism began to develop again and who presented large prostates, and the calls for help from patients with hemorrhage after years of normal function led us to question whether or not it might have been the better part of valor to have done an enucleation of the gland in the first instance.

*Delayed or Subsequent Resections*

| Condition | No. of Cases | Percentage |
|---|---|---|
| Retention | 58 | 5.42 |
| Hemorrhage | 30 | 2.83 |
| Carcinoma | 20 | 1.88 |
| Calculi | 22 | 2.0 |
| (*a*) Recurrent | 8 | |
| (*b*) Primary | 14 | |
| Total | 129 | 12.1 |

In regard to the subsequent procedures, the resections for carcinoma would be expected. It was, however, the subsequent resections done for retention, hemorrhage and calculi that somewhat tempered our judgment on the desirability of doing transurethral resections in all cases of prostatism. The shortest time interval between resections was one year; the longest interval was twelve years, and the average interval was six and seven-tenths years. Delayed hemorrhage is a troublesome and frightening symptom to a patient who has been well for years after his operation. It is admitted that bleeding relatively soon after the operation can be caused by a poorly nourished piece of residual prostate. When a patient has had several years without bleeding, and then bleeds, the bleeding has been found in most instances to be due to a recurrence of his prostatic growth.

### INFECTION

Infection is a problem to contend with in transurethral surgical procedures. The incidence has been greatly reduced with (1) the use of the antibiotic preoperatively and postoperatively, (2) the absence of the indwelling catheter preoperatively where possible, (3) the effort to have patients empty their bladders before leaving the hospital and (4) the early removal of postoperative catheters in patients that have not required postoperative drainage—sometimes within eighteen hours.

### COMMENT

It may seem, because of the emphasis on the complication previously cited, that we are trying to discredit the transurethral operation. Such is not the case. One learns by errors, and these errors have been helpful to us in our thoughts on transurethral resection.

Perusal of these complications has compelled us to modify our thinking somewhat about the method, and instead of 100 per cent resections, as was done in 1944, about 70 per cent of our cases are now done by the transurethral route. This leaves about 30 per cent for surgical enucleation. In this group are the younger age groups, with a longer life expectancy, the very large prostates in good surgical risks, the patients who come from remote regions, where it is impossible to follow them and offer help if the necessity for it arises, and the patients with fibrous prostates. That the transurethral method is the ideal procedure for the fibrous prostate cannot be questioned. The attempts at punching the vesical neck, with or without suprapubic drainage, prior to the advent of transurethral surgery, were for the most part unsuccessful in our hands. In cases of this type, after 1932, transurethral surgical treatment was given, with excellent postoperative results.

### SUMMARY AND CONCLUSION

One thousand and sixty-six cases of prostatism in which transurethral resection was done by the various members of the urologic staff of St. Luke's Hospital between 1935 and 1945 have been reviewed. The complications of this method are discussed. Transurethral resection, in our opinion, is a "minimal risk" procedure and was the ideal operation in about 70 per cent of our cases.

## ABSTRACT OF DISCUSSION

### ON PAPERS BY DR. DANIEL R. HIGBEE AND DRS. JOHN A. TAYLOR AND CHARLES H. PLACE

Dr. James Peters, Melbourne, Australia: I feel honored to discuss this paper in the place of my senior in Melbourne, Henry Mortenson. I bring you his thanks for your hospitality toward the Australians and very deep appreciation of your many kindnesses. The fact that he is returning, I feel sure, is not only a tribute to American urology but, speaking literally, is a confirmation of the fact that he drank deeply of your hospitality—and that is no reflection on your present climate. My first experience with papers delivered personally by an American was during the war in the Pacific. I then noticed how briefly and concisely and definitely the views were put forward. During my two years in England I have seen how eagerly read and attended are the papers in American medical literature. My impression after only two weeks in America is shown by these papers. There appears to be universal agreement that after general consideration of the patient the particular type of gland is treated by the method expressly suitable. The papers show that the various technics are mastered and applied and confirm the contention that the large gland is better treated by open operation, that operation in a manner which, in the hands of the particular surgeon, has shown the best results. I cannot discuss the paper on resection, by Drs. Taylor and Place, nor the paper by Dr. Higbee, because frankly, gentlemen, I am in this country to learn their particular technic.

Dr. Grayson Carroll, St. Louis: Running through these presentations on prostatic surgery is a note of optimism. Dr. Fishbein, in a meeting of the secretaries of the sections, remarked, "One of the outstanding contributions to medicine was the improvement in the treatment of bladder neck obstruction." Length of stay in the hospital reduced to ten days or two weeks, minimal amount of pain and complications during this period and a mortality rate of 1 per cent or less constitute convincing evidence of this statement. The approximation of the results in all types of surgical treatment makes one less enthusiastic in arguing about which is the best; one is content to say that the operation of choice is that one best suited to the operator, the patient and the type of gland. The urologist should be trained to perform any equally well, because they all have their place. Published figures of 5 per cent mortality in this type of operation are no longer valid. A mortality rate of 1 per cent and length of stay in the hospital of ten days to two weeks are not unique since the era of antibiotics, one stage prostatectomy and better understanding of electrolytic balance. Some of my confreres in St. Louis are meeting with a high degree of success by closing the bladder completely, leaving a small wick drainage in the suprapubic wound. We prefer to place a suprapubic tube for the first twenty-four hours as a safety valve during that critical period; my co-workers and I find that after the removal of the suprapubic tube next morning there is no urinary drainage on the dressings, which are not changed again for a week. It simplifies nursing and medical care and permits the patient to get up and about the second day without discomfort. We are satisfied with the technic described by Terrance Millen. The excellent view after the prostate is removed makes it possible to treat any abnormality of the bladder, such as fibrous bar or median lobe, easily. The Cherney incision, a double Gibson incision cutting directly through the recti muscles, gives a better exposure for the radical removal of the carcinomatous prostate, which is quite practical by this method. We inflate the bag within the bladder. Dr. Higbee's record of over 300 patients treated by the perineal prostatectomy demonstrates the value of this procedure. Its greatest value is the exposure of the posterior lobe, where early carcinoma is most commonly found and a frozen section can demonstrate the presence of carcinoma. The Papanicolaou test may offer us an opportunity to detect a malignant condition in a larger proportion of cases, making it imperative for the urologist to be familiar with the radical surgical removal, either by the perineal or the retropubic route. We should start a slogan: After 50 see your urologist for examination.

Dr. Vincent J. O'Conor, Chicago: I wish to express my appreciation for the painstaking review presented by Dr. Taylor and Dr. Place regarding their results in transurethral resection of the prostate. Their figures and end results, with special emphasis on application, more or less agree with mine and with those of other urologists who have had extensive experience in this field. My co-workers and I apply the procedure of transurethral resection to about 75 per cent of the patients we see with a vesical neck obstruction; the remainder are subjected to enucleation of the gland. Transurethral resection in our hands is followed by an annoying delayed hemorrhage from the bladder neck in too large a percentage of instances. Regardless of as complete a removal as possible and adequate control of infection, about 1 out of every 12 to 15 patients will have an episode of troublesome delayed hemorrhage from twenty-one days to several years after operation. For this reason we rarely do transurethral resection in large glands when the patient is going to return to an area remote from good urologic care. Stricture of the urethra continues to be a troublesome complication following transurethral surgical treatment. We feel that transurethral resection should be accorded to the majority of the patients that we see with obstructive prostatic lesions, but in approximately one fourth of these patients, in our experience, enucleation of the gland furnishes a more lasting and more satisfactory end result.

Dr. Nels F. Ockerblad, Kansas City, Mo.: A few years ago, such a symposium as this could not have been put on a program without causing considerable acrimonious debate. It is a sign that we, as urologists, have grown up when we can discuss and evaluate these divergent but efficient means of dealing with the problem of prostatism. As to Dr. Higbee's paper I should say little, for the simple reason that I have never been enthusiastic about the results in perineal prostatectomy. The operation itself from the operative point of view is fine. The transurethral operation has largely replaced it as an operation of choice in small to moderately enlarged prostates. The transurethral procedures as evaluated by Dr. John Taylor and Dr. Charles Place show that the operation of transurethral resection is no better than the operator. A comparatively unskilled surgeon may obtain very good end results in any of the open operations. In the transurethral procedure there is no place for the inept surgeon. In order to be satisfactory, this operation must approximate the clean removal of the suprapubic, perineal or retropubic enucleation. Until a few years ago, I contended that there were not more than 25 urologists in these United States who could do a really good transurethral prostatectomy. At the present time, I might raise that number slightly. Right now, the operation is suffering from a large number of inadequate resections. It is much better for a surgeon to concede that he cannot properly resect a prostate of over 50 Gm. than to attempt it and fail. Certainly, it was this operation that extended the limits of operability in prostatism, so that many aged sufferers who could not have had operative relief from prostatic obstruction can now be included as reasonable risks. The really great work of Reed Nesbitt took this operation out of the "punch operation" class and put it among the most highly technical of surgical procedures. There is a place for all of these operations, and every urologic surgeon should be not only familiar with each of these but also should be able to perform easily each of these operations.

Dr. Abraham Fleischman, Des Moines, Iowa: I was a participant in a dispute that occurred in this section more than a decade ago, when Dr. Morrissey was chairman and Dr. Herb was secretary—at that time I took issue with Drs. Elkhart and Thompson—in which I deprecated some of the shortcomings of transurethral resection. After more than a decade I want to retract what I said, that transurethral resection did not fulfil the certain requisites for proper removal of the prostate gland. I stated at that time that the procedure was limited only to the small gland. Today I want to say that the most dangerous procedure, as far as I am concerned, is the resection of the small gland, and not the moderately enlarged gland, and that I can do today a resection of a prostate up to 100 Gm. just as safely as I can a smaller gland. I would like to enumerate to you some of the difficulties and pitfalls in resecting some of the small glands. In the gland in which the fibrous tissue predominates, the so-called fibrous button, it is difficult to differentiate glandular tissue and fibrous tissue in some instances from the so-called false capsule. In the so-called large gland, in which the glandular tissue predominates, there is a great area which can be differentiated, and one can resect that particular gland because the glandular tissue does not approach the so-called fibrous capsule (by that I refer to the false capsule and not to the true capsule in its histologic structure). Then there is the so-called median bar, in which there is accentuation of the declivity of the posterior lip, which draws the verumontatum up close to the posterior lip. I have encountered many complications in this particular type of prostate, because in those instances the anatomic relations are distorted in a great measure. I do not agree with the protagonists of resection who insist that it is necessary to resect down to the true capsule. This complication of hemolysis that Dr. Foley and Dr. Creevy and other members of the Association have so carefully described can be averted if resection is limited to the so-called false capsule. The best results that I have had in transurethral resection have been in those cases in which only 18 to 25 Gm. of tissue have been removed.

Dr. Henry S. Browne, Tulsa, Okla.: Prostatic resection is strictly a cystoscopic procedure, and over a period of years I have evolved four simple cystoscopic rules for a successful resection which have stood the test of time. These are as follows: 1. With the sheath carefully centered and the verumontanum just visible, no prostatic tissue should fall into the open end of the sheath when it is rotated in a complete circle. 2. On examination with the retrospective telescope, the entire circumference at the junction of the operated area and the bladder should show no prostatic tissue projecting into the bladder at any point. 3. On examination of the prostatic cavity with the retrospective telescope, no tissue should be seen projecting into the cavity. 4. The verumontanum should be completely visible with the retrospective telescope. If these requirements are fulfilled, one can be assured of a good result in practically every case, as the chances of human error are reduced to a minimum. Better than 90 per cent of the hypertrophied gland will have been removed, so that the chances of recurrence are no greater than in other types of prostatectomy. Up to June 15 of this year, I have done 178 consecutive resections without a death. In 3 cases I had previously done resections from six to twelve years before. Two patients had previously had a prostatectomy. During this period two prostatectomies were done. Transurethral resection, when properly done, will give results as good as, or better than, any other type of prostatectomy with less mortality, less hospital stay and greater postoperative comfort to the patient. If results are not good it is not the fault of the resection, but of the resectionist.

Colonel J. C. Kimbrough, Washington, D. C.: During the twenty-nine month period ending June 1, 1948, one hundred and eighty-four operations for prostatic diseases were performed at Walter Reed General Hospital: endourethral resection, 92; perineal, 83; suprapubic, 5, and retropubic, 4. One hundred and fifty-one operations were performed for benign disease, hyperplasia and calculi and 33 for malignant disease. The operations performed for benign disease were endourethral resection, 86; perineal, 77; suprapubic, 5, and retropubic, 3; for malignant disease the incidence was perineal (radical 24, conservative 2), 26; endourethral resection, 6, and retropubic, 1. The diagnosis in the 33 cases of malignant conditions of the prostate was established prior to operation or at operation in 31 patients. The diagnosis in 2 patients was made on laboratory examination. The radical procedure was carried out in all those except in 1 patient, 81 years old, in 1 with missed diagnosis and in 6 considered inoperable for whom endourethral resection was performed. Radical operation was feasible in 24 of the 33 patients (77.7 per cent). Endourethral resection is the treatment of choice in benign glands of grade I enlargement (usually not more than 60 Gm. of tissue were removed) and to relieve obstruction in advanced malignant conditions. Perineal prostatectomy is the operation of choice for large glands and malignant tissue amenable to radical removal. The suprapubic and retropubic operations were carried out for resident training purposes. It was necessary to open the wound for control of hemorrhage in two perineal operations and one retropubic operation. Urinary incontinence was rare in all the cases in which operations were performed except in the case in which there was radical operation for a malignant condition. Urinary incontinence was present in 3 of the 24 cases of radical operation (16.6 per cent). Incontinence is defined as the necessity for using an apparatus for urinary control. Sexual impotence is a frequent and serious squela of perineal prostatectomy.

Dr. Daniel R. Higbee, Denver: I should like to thank the discussants who agree that perineal prostatectomy still has a place in modern urology, particularly Dr. Morrissey, for his discussion and support, Dr. Ormond and Col. Kimbrough for pointing up my purpose in presenting this series of cases. If the public, through education, expects to be cured of prostatic malignant disease, we doctors should emphasize the need for repeated periodic examination and should be able to offer surgical treatment at a time when a cure may be expected. The fact that, by routine examination, Col. Kimbrough could detect such a large number of malignant conditions which were operable, is something which we cannot pass off lightly. I realize that the perineal operation is not popular, that it may be difficult and that at times it strains one's ingenuity; however, we are going to have to do more perineal operations and cure more persons of prostatic cancer if we are to maintain our prestige in our field of medicine.

# SELECTIVE UTILIZATION OF BARBITURATES

## As Illustrated by a Study of Butabarbital Sodium (N. N. R.)

ROBERT D. DRIPPS, M.D.
Philadelphia

Since the introduction of barbital in 1903, hundreds of barbituric acid derivatives have been synthesized and studied both pharmacologically and clinically. While these derivatives resemble one another in action, their effects on the central nervous system are not identical. Some have more tendency to produce excitement than others. Their depressant actions on various components of the central nervous system differ. Variations are noted in onset, intensity and duration of action and in the fate of these substances in the body. Some act promptly, powerfully and briefly and are destroyed in the body. Others are slower in action and milder, act over longer periods of time and are in large part excreted unchanged.

Qualitative differences among the barbiturates enable the clinician to select a specific barbiturate for a specific purpose, i. e., anticonvulsant, hypnotic, sedative or anesthetic. By the same token the physician should also take full advantage of the quantitative variations in actions offered by the drugs. For example, in the field of hypnosis, by varying the choice of the agent, one can provide sleep early in the evening or late in the night, of mild or intense degree or of short or long duration.

The purpose of this paper is to develop this thesis of selective utilization of the barbituric acid group and to illustrate the concept by reference to a new member, butabarbital sodium N. N. R. (sodium 5-ethyl-5-*sec.* butyl barbiturate),[1] the first extensive clinical survey of which, on 630 patients, is presented here.

### PHARMACOLOGIC ASPECTS

A comprehensive investigation of the pharmacologic characteristics of butabarbital in animals has been made by Gruber, Ellis and Freedman.[2] These workers compared the drug to pentobarbital sodium, barbital and phenobarbital. Their results can be summarized as follows: Butabarbital was almost as prompt in action as pentobarbital sodium; it was intermediate between the short-acting and long-acting derivatives as far as duration of effect was concerned; it was more potent than phenobarbital and barbital and less potent than pentobarbital sodium. The drug appeared to be destroyed in the body, probably in the liver. There was no evidence of chronic toxicity even after six months of daily administration. Effects on the circulation, cardiac rhythm and respiration were similar to effects of other barbiturates.

Given a drug with these characteristics, one should be able to make a reasonable prediction as to its clinical utility. It would seem that this new barbiturate might be valuable in patients with renal disease in whom sedation was required. It should compare favorably with, or surpass, phenobarbital in the production of mild prolonged sedation. It should be useful as a sedative in aged persons. It probably would not be the drug of choice when an intense effect or a rapid action was desired. These possibilities have been confirmed and extended by this study.

### METHOD OF STUDY

Three groups of patients were treated. The first group of 155 patients required hypnosis at bed time. The second group of 100 patients received the drug because of a variety of diseases requiring prolonged yet relatively mild sedation. The third was composed of 375 patients given butabarbital sodium as part of their preparation for surgical treatment, i. e., preoperative sedation. Dosage ranged from 15 to 300 mg. by mouth.

Data obtained on each patient included a history of previous experience with other sedatives (dose, type of drug, untoward reactions and subjective evaluation), a history of renal or hepatic disease (supplemented by laboratory studies of renal and hepatic function if indicated), observations on the onset, duration and intensity of action of butabarbital sodium, on sequelae following its administration (such as headache, gastrointestinal upset, dulness and irritability) and on the response of blood pressure, pulse rate and respiratory rate.

### RESULTS

1. *General Properties.*—On the basis of data obtained from the 630 patients, certain general characteristics of butabarbital sodium can be described. The onset of action averaged between fifteen and thirty minutes after ingestion. The peak of action was generally reached within one and a half hours, and activity began to diminish in four to five hours. According to the classification of Fitch and Tatum[3] these properties would place butabarbital sodium in the intermediate group of barbituric acid derivatives from the point of view of onset and duration of action. The intensity of action of the drug can be defined as mild, resembling that of phenobarbital much more than that of the shorter-acting barbiturates, such as pentobarbital sodium, "amytal" (5-isoamyl-5-ethylbarbituric acid) or "seconal sodium" (sodium 5-allyl-5-[1-methylbutyl] barbiturate).

2. *Toxicity.*—No acute toxicity was observed, although the administration of 300 mg. by mouth in a single dose was followed by nausea and vomiting within fifteen to forty minutes in 16 per cent of the 55 patients receiving this amount. Gastric irritation from the large dose of barbiturate is suggested as the most likely explanation for this disturbance. The incidence and severity of "hangover" reactions will be discussed later. No significant respiratory depression was noted.

Several patients with impaired hepatic function were given 200 mg. of butabarbital sodium. Surprisingly little alteration in the intensity or duration of action was noted.

This should not be taken as an index of the safety of butabarbital sodium in the presence of hepatic damage. The studies of Gruber and his co-workers[2] indicate that the drug is destroyed in the body. The inference is that part or all of the detoxification takes place in the liver. It is well known that such substances may act more intensely and for a prolonged period when administered to patients with hepatic disease. That my few patients did not show such a response may be only coincidence or may be related to the relatively moderate degree of impairment of function. Hepatic disease of any extent should be regarded as a contraindication to the use of all barbiturates which are detoxified by this organ.

[3] Fitch, R. H., and Tatum, A. L.: Duration of Action of Barbituric Acid Hypnotics as a Basis of Classification, J. Pharmacol. & Exper. Therap. **44**: 325 (March) 1932.

There was no evidence of chronic toxicity. Thirty patients received the drug daily in doses of 50 to 100 mg. for periods of three to six months.

*3. Hypnosis.*—Butabarbital sodium was administered to 155 patients in 0.1 Gm. doses for the purpose of hypnosis. The patients were observed directly for a hypnotic effect and were questioned the following morning as to immediate and delayed subjective reactions. Twenty persons (13 per cent) showed no response to the drug; the remainder were either quieted in varying degrees or actually went to sleep.

Before one can consider the value of butabarbital sodium as a hypnotic, certain facts regarding insomnia should be understood. In some persons the major problem is that of getting to sleep. Once asleep these patients remain asleep for the rest of the night. In such circumstances the hypnotic of choice is one with a prompt and intense onset of action. In this category belong the shorter-acting barbituric acid derivatives. On the other hand, there are other patients who fall asleep without drugs, but who awaken in the early morning and toss restlessly for the remainder of the night. This is common in aged persons. For these the ideal hypnotic is one with a delayed onset of action and a less intense but more prolonged depression. Butabarbital sodium is extremely useful in these instances. A combination of the two types of insomnia can be treated readily by combining butabarbital sodium with a short-acting barbiturate.

One of the major objections to hypnotics is the "hangover" syndrome noted by many patients the morning following ingestion. The longer the duration of action of the depressant drug the greater will be its tendency to produce dulness, logginess, irritability or headache as an after-effect. The incidence of these side reactions in the 155 patients in this group was as follows: 28 (18 per cent) experienced dulness, weakness, dopiness or grogginess and 12 (8 per cent) experienced headache.

The utility of a particular hypnotic depends also on the cause of the insomnia. The barbiturates as a group possess no analgesic properties. They are of no value, therefore, in the relief of insomnia resulting from pain, and they are not so useful as other drugs in the treatment of insomnia related to dyspnea. Indeed, barbiturates are often contraindicated in the management of these patients, since the depression of judgment, volition and other higher cortical functions may render the patient excitable and uncontrollable. The role of the barbiturates in insomnia is therefore primarily in the management of the tense worried nervous person rather than the patient unable to sleep because of organic disease. The mild relatively prolonged action of butabarbital sodium makes this substance of value to many of the former patients. The "hangover" syndrome may militate against the general adoption of the drug as a hypnotic. This is as it should be, for a physician must treat each patient individually and cannot expect to employ a single hypnotic for all types of insomnia or for every person.

This study also served to reemphasize a point often overlooked by physicians in the prescription of a depressant drug to patients who may assume the upright position during the course of the drug's action. Although measurements of the circulation (cardiac output, pulse rate and blood pressure) are essentially normal in persons receiving narcotics as long as they remain supine, major changes are noted in many patients when they are placed in the head up position.[4] Such drugs apparently depress the vasomotor center and produce dilatation of certain vessels in the periphery. The body is thus less able to compensate for the circulatory stress of the upright position, and syncope results in a definite proportion of cases. In 1 patient who attempted to walk to the bathroom after receiving the sedative, a precipitous fall in blood pressure occurred, followed by loss of consciousness and epileptiform convulsions secondary to cerebral anemia. This same sequence of events has been noted after administration of morphine and meperidine hydrochloride.

*4. Prolonged Sedation.*—A tremendous quantity of barbituric acid derivatives are being prescribed by physicians today for the symptomatic treatment of a variety of functional and organic diseases. Phenobarbital is used in the majority of these instances, primarily because the shorter-acting derivatives (pentobarbital sodium, "seconal sodium" and "amytal") are too intense in their effect and act for too brief a period. Phenobarbital is destroyed in part in the body but is also eliminated as such by the kidneys. Impairment of renal function, therefore, may increase the toxicity of phenobarbital. Theoretically, butabarbital sodium would be useful as a substitute for phenobarbital in patients with renal damage who require sedation. Many aged persons might be included in this category. In addition, it appeared that the mild prolonged sedation of the drug might make it useful in a variety of conditions in which such therapy is indicated.

For these reasons 100 patients were given butabarbital sodium primarily for prolonged daytime sedation. The indications for treatment included:

| | | | |
|---|---|---|---|
| Hypertension | 17 | Osteoarthritis | 2 |
| Epilepsy | 17 | Tabes | 2 |
| Hyperthyroidism | 10 | Nephritis | 1 |
| Anxiety states or menopausal neurosis | 10 | Peptic ulcer | 5 |
| Congestive heart failure | 10 | Retinal detachment | 5 |
| Coronary occlusion | 5 | Subacute bacterial endocarditis | 2 |
| Bronchial asthma | 2 | Ulcerative colitis | 2 |
| Buerger's disease | 2 | Regional ileitis | 2 |
| Angina pectoris | 2 | Spastic colon | 2 |
| | | Acute rheumatic fever | 2 |

The age of the patients ranged from 7 to 75 years. The dose of the drug varied from 15 to 50 mg., three to four times a day. The smaller doses were much more satisfactory, for amounts in excess of 30 mg. tended, in female patients particularly, to produce excessive sedation, depression and headache. Dose for dose, butabarbital sodium was more intense in its action than phenobarbital. At 15 mg. levels, however, the two drugs were about equal as far as use in adults was concerned. Relief of tension, diminution in anxiety and reduction in nervousness was evident as soon as the proper dose schedule was reached.

Twenty-five of the patients in the group were outpatients. The nervous component of the medical problem in these patients was improved or eliminated in many instances by use of the elixir as a vehicle for other indicated medication. Such complaints as the "dizziness" associated with hypertension or menopausal changes, insomnia, anxiousness and nervous tension were relieved in the majority of instances. The patients expressed themselves as "feeling more relaxed," "much quieter," "less nervous" and "sleeping better." An occasional patient complained of headache within an hour of ingestion of the drug. Others spoke of being too "dopey." As a rule these complaints were eliminated by reduction in the dose of the drug.

[4] Drew, J. H.; Dripps, R. D., and Comroe, J. H., Jr.: Clinical Studies on Morphine: II. The Effect of Morphine upon the Circulation of Man and upon the Circulatory and Respiratory Response to Tilting, Anesthesiology **7**: 44 (Jan.) 1946. Dripps, R. D., and Comroe, J. H., Jr.: Circulatory Physiology: The Adjustment to Blood Loss and Postural Changes, S. Clin. North America **26**: 1326 (Dec.) 1946.

The sedation for 17 patients with thyrotoxicosis being prepared for surgical intervention was provided by butabarbital sodium. In these patients the sedation afforded was helpful in the reduction of the basal metabolic rate. In 1 patient, apparently ready for operation and given butabarbital sodium for preoperative sedation, tachycardia developed (pulse rate 168) just prior to the induction of anesthesia. This may have been related to depression of the cardiac vagus, although Gruber and Keyser[5] reported that this drug is a much weaker vagal depressant than pentobarbital sodium or "seconal sodium."

Fifteen of the patients receiving prolonged sedation were 65 years of age or older. The results of 15 mg. doses in these patients were remarkably good. The patients were suffering from such conditions as peptic ulcer, coronary occlusion, hyperthyroidism, congestive heart failure and hypertension. Ten other patients were in the 60 to 65 year age group. The incidence of headache and logginess was lower in these older persons than in the younger subjects.

As indicated in the tabulation, 17 patients with idiopathic epilepsy were treated with butabarbital sodium. Some of these received the drug for six months. All had been getting phenobarbital. Three of the 17 were not as well controlled by butabarbital sodium, 12 noticed no difference and 2 stated the belief that they had less frequent seizures. My impression is that butabarbital sodium can replace phenobarbital in the treatment of epilepsy but offers no advantage over the latter drug.

5. *Preoperative Sedation.*—The ideal barbiturate for preoperative sedation would be a compound which was effective promptly when taken by mouth, would produce a distinct depression of the psyche without excitation and without affecting the circulation and respiration, would begin to wear off in two to three hours and would be free from "hangover effects." Although such a drug does not exist, certain of the short-acting members of the series are preferable to butabarbital sodium when judged by these criteria. Data obtained from 375 patients who received butabarbital sodium prior to operation substantiate this statement.

The mild depression produced by butabarbital was not sufficient to produce tranquillity in the face of an acute stress. Moreover, the prolonged action hampered early ambulation in certain patients. Barbiturates which act more intensely, more promptly and for a shorter period of time are preferable in these circumstances.

## COMMENT

An analysis of the results obtained with butabarbital sodium indicates that this drug should be classed as an intermediate barbituric acid derivative from the point of view of onset, intensity and duration of action. It would appear that its greatest usefulness should be in the field of daytime sedation. The mild relatively prolonged action of the drug makes it suitable for management of many functional disorders and for the treatment of the nervous tension and anxiety associated with certain organic diseases, such as hyperthyroidism, peptic ulcer, hypertension, spastic colon and ulcerative colitis. Being independent of the adequacy of renal function as far as toxicity is concerned, it should be valuable in the treatment of patients with renal damage who require sedation or hypnosis. Anxiety states in the older age groups appeared to respond well to small doses of the sedative.

There are certain indications for barbiturate therapy in which butabarbital sodium would not be the drug of choice. Our results suggest that its intensity of action is not sufficient for this substance to be particularly useful as a preoperative sedative. Likewise, the slower onset and relative mildness make butabarbital sodium less efficient for immediate hypnosis than some of the shorter-acting more potent barbituric acid derivatives. In the therapy of epilepsy this substance appears to have no advantage over phenobarbital.

The balance sheet, therefore, can be regarded as showing both favorable and unfavorable items as far as butabarbital sodium is concerned. A similar analysis of other currently popular barbiturates would reveal much the same lack of balance. No one substance can be expected to meet all requirements or to be of value in all circumstances. The physician must select from the available drugs particular agents for specific indications. He should become familiar with the characteristics of a number of barbituric acid derivatives and prescribe the one which meets the needs of each person. Viewed in this way, the chief indications for butabarbital sodium would be prolonged daytime sedation and, secondarily, "delayed" hypnosis.

## SUMMARY

A clinical survey of the characteristics and utility of a new barbituric acid derivative, sodium 5-ethyl-5-*sec.* butyl barbiturate (butabarbital sodium N. N. R.) has been made on 630 patients. The drug was found to be intermediate among barbiturates in respect to onset, intensity and duration of action. Because of its mild and relatively prolonged action, butabarbital sodium proved particularly useful in the field of daytime sedation and "delayed" hypnosis. Selection of specific barbiturates for specific purposes is urged.

---

**Some Functions of the Placental Trophoblast.**—The trophoblastic chorionic epithelium is the essential parenchyma of the placenta. The trophoblast provides for the nutrition of the embryo by the destruction and absorption of parts of the uterine decidua and by the absorption of metabolities from the maternal blood circulating in the intervillous space. The transfer of various metabolites as well as the destruction of parts of the decidua is mediated by a variety of enzymes and chemical processes, some of which it is possible to study by histochemical means. In addition to these functions it has become evident in recent years from endocrinologic and chemical investigations that the placenta is an important endocrine organ which forms and secretes both steroid and chorionic gonadotrophic hormones. The formation of these lipid and protein bodies involves complex metabolic syntheses. The trophoblast is very rich in cytoplasmic ribonucleoproteins as can be demonstrated by suitable histochemical methods. The presence of a great amount of this substance in the early part of gestation suggests that the placenta is an important site of protein synthesis.—George B. Wislocki, M.D.; Edward W. Dempsey, Ph.D., and Don W. Faucett, M.D., Some Functional Activities of the Placental Trophoblast, *Obstetrical and Gynecological Survey,* October 1948.

# GASTROSCOPIC APPEARANCES FOLLOWING VAGOTOMY

## With Significance of Observations in Relation to Gastric Innervation

MOSES PAULSON, M.D.
and
EUGENE S. GLADSDEN, M.D.
Baltimore

This communication deals with gastroscopic observations following vagotomy alone and in conjunction with either gastroenterostomy or subtotal gastrectomy in the treatment of peptic ulcer. The observations for the most part were made during the first postoperative year.

### MATERIAL

This material was divided into three groups:

1. Simple vagotomy, for conditions without abnormal communication between the stomach and the intestine. Included are cases in which supradiaphragmatic vagotomy was done ten to fourteen days following suturing for a perforated peptic ulcer (10 cases).
2. Vagotomy with gastroenterostomy (5 cases).
3. Vagotomy with subtotal gastrectomy (9 cases).

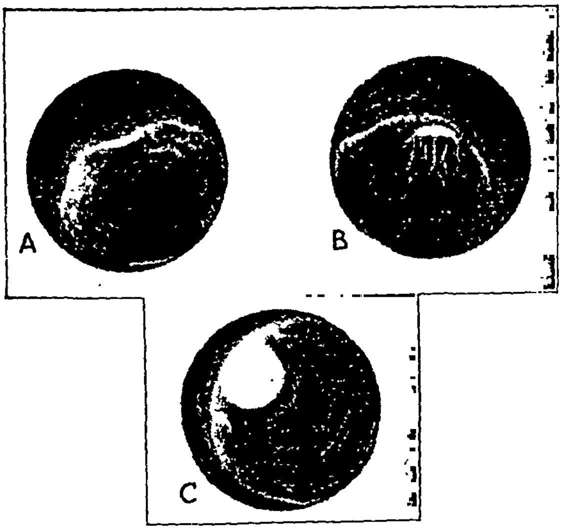

Fig. 1.—*A*, Results six months after suturing of perforated duodenal ulcer and transthoracic vagotomy. The reaction to the insulin test was negative. Relative peristaltic inactivity and patulousness of the antrum and the pylorus were present. The antrum covers most of the pyloric sphincter. *B*, one year after suturing for perforated duodenal ulcer with transthoracic vagotomy. The reaction to the insulin test was positive. Unusual occurrence of decided peristaltic activity of the antrum and pyloric sphincter. *C*, seven months after suturing for perforated ulcer with transthoracic vagotomy. The reaction to the insulin test was negative. There was the usual picture of peristaltic inactivity and patulousness of the pylorus.

### RESULTS

1. *Simple Vagotomy.*—In cases in which simple vagotomy was done the stomach was usually found to be large and atonic, with little evidence of peristaltic activity. There was no edema, thickening, erythema or friability, and the mucosa was of normal color. No significant alterations were noted in the rugal pattern. The antrum was usually dilated or atonic and relatively devoid of peristalsis. The pyloric sphincter was seen completely with ease, a condition which does not generally obtain in the nonvagotomized stomach, where only occasional glimpses of the pylorus are observed in whole or in part (fig. 4). This structure was unexpectedly observed to be patulous and continually open, except at such times when an occasional peristaltic wave passed over and momentarily contracted it. The pyloric entrance was wider than is seen in normal circumstances (fig. 1 *A* and 1 *C*). Within the first year, a tendency toward restoration of normal tone and peristalsis was noted (fig. 1 *B*). No consistent relationship could be demonstrated between these changes in the stomach and "positive" or "negative" reactions to insulin tests which indicate incomplete and complete bilateral vagotomy, respectively.

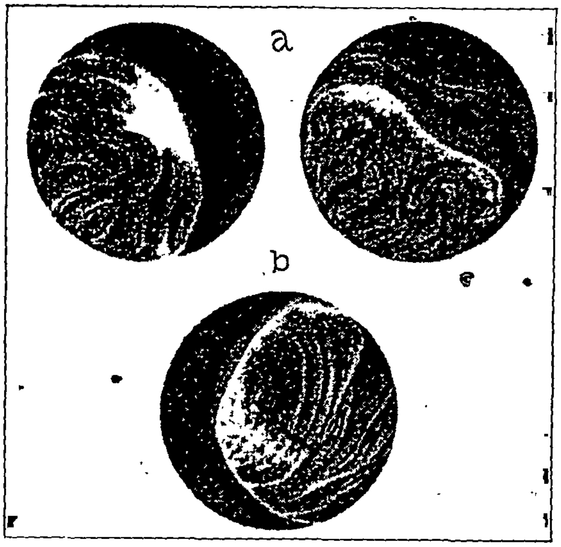

Fig. 2.—Gastroenterostomy and vagotomy of six months' duration, showing flaccidity of the antrum and pyloric sphincter (*a*) as well as patulousness of the stoma (*b*); here, too, there is negligible peristaltic activity.

2. *Vagotomy with Gastroenterostomy.*—All changes noted previously, including patulousness of the pylorus, were seen. The stomal openings tend to be more patulous and less active than is seen in gastroenterostomy without vagotomy (fig. 2). In addition, mucosal alteration of a superficial nature, consisting of erythema and rarely of edema and thickening, was encountered.

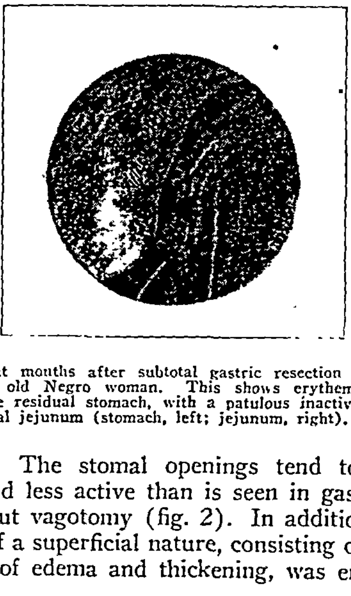

Fig. 3.—Eight months after subtotal gastric resection with vagotomy in a 62 year old Negro woman. This shows erythema, edema and friability in the residual stomach, with a patulous inactive stoma and a relatively normal jejunum (stomach, left; jejunum, right).

Here the insulin test not infrequently is of questionable value, because of reflux of alkaline intestinal contents into the stomach.

3. *Vagotomy with Subtotal Gastric Resection.*—In every case there were fairly pronounced mucosal changes in the residual gastric pouch, erythema and thickness, with occasional edema (fig. 3). The stomal openings were usually larger than one usually sees in subtotal gastrectomy,[1] and the jejunum evidenced relatively mild mucosal change on one occasion. In cases in which insulin tests were made, the reactions were negative. However, this test is unreliable in subtotal gastrectomy, because of the reduced gastric secreting mucosa and to the regurgitation and admixture of intestinal contents.[2]

4. *Controls.*—The dilated, relatively inactive stomal opening, the semiquiescent antral atony and particularly the patulousness of the pylorus are not due to morphine, atropine and phenobarbital sodium given by us hypodermically one-half hour preceding gastroscopy as a step in preparation of this examination. Such administration in those with similar conditions but without vagotomy generally fails to reveal these gastroscopic changes.

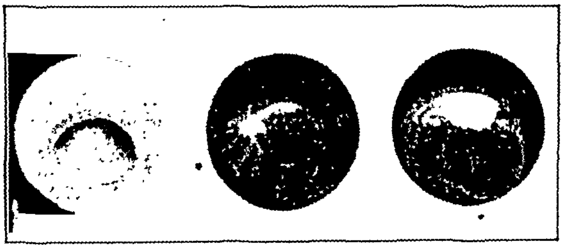

Fig. 4.—Six months after simple suturing of perforated duodenal ulcer without vagotomy. Successive stages of a peristaltic wave passing through the antrum and pylorus. Here tone, peristaltic activity and behavior of the pylorus were normal. (Contrast with figure 1 *C*.)

COMMENT

Because of existing data, gastric atony or dilatation, peristaltic inactivity and varying degrees of retention of gastric contents were expected. Such changes as easier visualization of the pylorus, and mucosal alteration in those cases in which the condition was associated with gastroenterostomy and subtotal gastric resection can also be explained. Pyloric visualization is easier possibly because of the dilatation of the stomach, allowing for deeper introduction of the gastroscope, as well as increased antral size. The mucosal changes seen here are similar to mucosal changes seen in cases of subtotal gastric resection without vagotomy.[3] Therefore, vagotomy *per se* does not protect against the gastritis of the postoperative stomach. The mucosal changes are chiefly gastric. The jejunum, the usual site of marginal ulceration when it occurs, appears to be less involved.

We are impressed with the observation that the greater the disturbance of gastric structure and function, the greater the gross mucosal alteration. Thus, in simple vagotomy there is negligible change; where gastroenterostomy is added, it is somewhat more definite, but it appears greatest in subtotal gastrectomy, with or without vagotomy.

It is generally accepted that stimulation of the vagus nerves (parasympathetic), as they pertain to the stomach, usually causes increased gastric tone and peristaltic activity and relaxation of the pyloric sphincter. Stimulation of the sympathetic nerve supply to the stomach has the opposite effect.[4] Therefore, it was to be expected that section of the parasympathetic (vagus) nerve supply to the stomach would create a state of autonomic imbalance wherein the sympathetic influence would act relatively alone, unopposed by the antagonistic effects of the parasympathetic system. The resulting effect would be comparable to sympathetic stimulation with resulting gastric atony, peristaltic inactivity and pyloric contraction. As already noted, although the effect on the stomach is what was anticipated, the influence on the pylorus appeared to be just the opposite of that expected, namely, patulousness.

This observation has been confirmed by our surgeons on reoperation in 3 cases of simple vagotomy because of resulting intractable gastric dilatation and retention. They commented on the "patulousness of the pyloric canal," that more fingers can be inserted into the pylorus than is ordinarily possible in cases without vagotomy and that there was no obstruction of the pyloric outlet. Thus, it would appear that gastric emptying may be more dependent on gastric tone and peristalsis than pyloric tonicity when bilateral vagus section has been performed.

This apparent occurrence of an "open" pylorus rather than expected contraction on vagal section would suggest that the generally accepted hypothesis of a reciprocal effect between the stomach and the pylorus on stimulation of the components of the autonomic nervous system requires further investigation and review.

SUMMARY

Gastroscopic studies were carried out in 24 cases with vagotomy alone, with gastroenterostomy and with subtotal gastric resection made during the first postoperative year. In simple vagotomy, the observations were gastric dilatation and atony, peristaltic inactivity and lack of mucosal change. An unexpected observation was patulousness of the pylorus rather than the anticipated contraction. This observation at the pylorus casts doubt on the accepted theory of reciprocal effect of the autonomic nerve supply on the stomach and pylorus. It stresses the importance of gastric tone and peristalsis, rather than pylorospasm, in postvagotomy gastric retention.

In vagotomy with gastroenterostomy the mucosal changes were not as pronounced as in those with vagotomy and subtotal gastrectomy. In both instances, the stoma was patulous and relatively inactive. In some instances, after many months, a tendency to reversion to normal tone was noted, but the mucosal alterations, particularly in subtotal gastrectomy, tended to persist. Since similar mucosal changes are seen in similar circumstances in those without vagotomy, vagotomy per se does not protect against postoperative gastritis and jejunitis.

## DEATH FOLLOWING USE OF TETRAETHYLAMMONIUM CHLORIDE

RICHARD P. LASSER, M.D.
NORMAN ROSENTHAL, M.D.
and
LEO LOEWE, M.D.
Brooklyn

The autonomic blockading effect of the tetraethylammonium ion was first reported by Acheson and Moe[1] in 1945. Because of the multitude of possible therapeutic and diagnostic uses, this drug has received increasing clinical application. Reports of its use in hypertension,[2] causalgic states, peripheral vascular disease, coronary artery disease and gastrointestinal tract disease have appeared recently. In the vast majority of instances of its use, the effects produced were transient and inconstant and consisted mainly of a slight to moderate fall in blood pressure,[3] tachycardia, decreased venous pressure, increased blood flow to the extremities, cutaneous flush, increase in skin temperature and decrease in sweating, salivation, bladder tone and gastrointestinal tract motility.[4] All effects are apparently due solely to blockage at the peripheral autonomic ganglions of sympathetic and parasympathetic outflow. Toxic effects have been infrequent. The outstanding adverse effect has been noted in a small group of hypertensive patients in whom a severe depression of the blood pressure with associated vascular collapse and signs of cerebral anoxia[3] have been observed. One similar severe shocklike reaction in a patient with a normal blood pressure has also been recently reported.[5]

These toxic reactions all resulted in complete recovery, and to our knowledge the case here being reported is the first death attributable to tetraethylammonium chloride.

### REPORT OF A CASE

*First Admission.*—The patient was a 33 year old white woman who had been symptomatically well until six weeks before her first admission, in July 1947, at which time diplopia suddenly developed followed a day later by left abducens paralysis. Her systolic blood pressure was 240 mm. of mercury at that time and remained continuously elevated thereafter. Her eye signs cleared in about ten days, and then frontal and occipital headaches of moderate intensity developed. She was reported to have had albuminuria but no hematuria, and no past history of renal disease was elicitable. She had lost 12 pounds (5 Kg.) in the six weeks preceding admission. A family history of maternal hypertension was present. She was admitted to the surgical service for the purpose of having a sympathectomy.

Results of Physical Examination: The patient's temperature was 98.2 F., the pulse rate 80, respirations 16 and blood pressure 260 systolic and 150 diastolic. She was moderately anemic but in no distress. The salient physical observations were as follows: There was some exophthalmos. The optic disks showed some haziness of their borders but no elevation; the arterioles were spastic, and there were cotton-wool type exudates bilaterally. Examination of the heart revealed the point of maximal impulse to be in the sixth intercostal space at the midclavicular line. The sounds were of good quality, with the aortic second sound tambour-like and greater than the pulmonic second sound in intensity. There were no murmurs or thrills. No signs of cardiac decompensation were present. The impression on admission was that the patient had essential hypertension, with chronic glomerulonephritis and pheochromocytoma to be considered.

Laboratory Data: The hemoglobin was 70 per cent, the red blood cell count 3,730,000 and white blood cell count 7,000, with a normal differential count. The urine was acid, with 2 plus albumin, no sugar and occasional white cells. The concentration test showed a maximal concentration of 1.018. Blood sugar was 80 and urea nitrogen 18.0 mg. per hundred cubic centimeters. Urea clearance was 28.6 per cent of normal and the basal metabolic rate + 14 per cent. The electrocardiogram showed regular sinus tachycardia, no axis deviation, with the R-T segment in leads 2 and 3 depressed and the T wave diphasic in lead 2 and inverted in lead 3. A roentgenogram of the chest revealed some rounding of the left ventricle. Intravenous pyelography showed rather small kidneys with good function bilaterally and no deformity of the pelvis or the calyceal system.

A "sodium amytal" N. N. R. (sodium isoamylethylbarbiturate) test was done, with an initial blood pressure of 250 systolic and 150 diastolic and a maximal decline to 160 systolic and 120 diastolic several hours after heavy sedation.

A medical consultant was of the opinion that this was a case of chronic glomerulonephritis with secondary hypertension and felt that surgical intervention was not advisable. The patient was discharged.

*Second Admission.*—She was admitted to the medical service of this hospital on March 8, 1948, about eight months after her discharge. Eight months and six months previously she had been hospitalized elsewhere and had undergone a two stage sympathectomy with removal of the sympathetic chain bilaterally from the level of the fifth thoracic to and including the third lumbar ganglion and removal of the splanchic system to the celiac plexus. Her blood pressure had only a transient fall to below 200 mm. of mercury, but her headaches disappeared almost completely. Five weeks before this final admission she began to have a sanguinous discharge of moderate proportions from the vagina, which continued intermittently until the day of admission. For four weeks she had nausea and vomiting. One week before admission her eyesight became poor, and there was rapid progress to almost complete blindness. For five days she had steady throbbing retro-orbital headache. For two days there had been epistaxis. Physical examination revealed a pale cachectic white woman with pronounced proptosis and almost complete loss of vision. The ocular fundi were the seat of advanced hypertensive changes, with obscuration of the disks by large exudates and many recent and old hemorrhages spread throughout. There were bloody incrustations in the nose and blood on the posterior pharyngeal wall. The lungs had diminished resonance and distant breath sounds throughout. The heart was enlarged to the left, with the mitral second sound and the aortic second sound accentuated, and there were no murmurs or thrills. Blood pressure was 220 systolic and 100 diastolic. No peripheral edema or venous engorgement was noted. The clinical impression was that she had essential hypertension rather than hypertension secondary to renal disease.

Laboratory Data: Urinalysis revealed albumin (2 to 3 plus), with varying quantities of red and white cells; maximum specific gravity was 1.010. The hemoglobin was 55 per cent, red blood cell count 2,600,000 and white blood cell count 18,000, with 85 per cent polymorphonuclear leukocytes. The platelet count was 175,000 per cubic millimeter. Bleeding time was ½ minute and clotting time 2½ minutes. Blood sugar was 110 and urea nitrogen 78.4 mg. per hundred cubic centimeters. Cholesterol was 220 and esters 147 mg. per hundred cubic centimeters. The blood culture was negative.

The patient's course was relentlessly downhill, with persistent and sustained hypertension. Inasmuch as there seemed little else to offer her it was decided to give tetraethylammonium chloride to see whether her hypertension could be modified and whether this would aid in producing a clinical remission and symptomatic relief. On March 12, at 6:45 p. m., 5 cc. (500 mg.)

of tetraethylammonium chloride ("etamon") was given intravenously over a five minute interval. Within thirty minutes the blood pressure had fallen from 230 systolic and 140 diastolic to 60 systolic and 20 diastolic, and the patient was cyanotic, comatose and in evident shock with belabored respiration. Nikethamide ("coramine") and epinephrine were given intravenously and later by the intracardiac route. By 10:30 p. m. the blood pressure had returned to 120 systolic and 90 diastolic, but her respirations were slow (8 to 10 per minute) and she appeared only little improved. Her pulse rate was 110 and thready, and her skin was cold and moist. Her blood pressure again fell to shock levels, and at 12:30 a. m., slightly less than six hours after the administration of the tetraethylammonium chloride, she died.

*Postmortem Observations.*—At autopsy, numerous ecchymoses were seen scattered over the trunk and extremities and a bloody discharge from the nose and vaginal orifice was present. There was 150 cc. of clear amber fluid in each pleural cavity. In the heart subepicardial petechiae were present. The papillary muscles of the left ventricle were hypertrophied; the left ventricular cavity was dilated, and the interventricular septum bulged into the right ventricle. Coronary arteries showed moderate atherosclerosis, but no narrowing of the lumen. The lower lobes of both lungs were beefy red and airless. The pancreas was intensely congested. Pinhead-sized circular hemorrhagic areas were scattered over the surface of the kidneys.

Microscopic Data: Widespread arteriolonecrosis was evident in the spleen, adrenals, ovaries and, to a lesser extent, pancreas and kidneys. Small-sized arteries were also occasionally involved by the same process. Sections from the heart showed only hypertrophy of the myocardial fibers and no myofibrosis. The alveoli of all lung sections were filled with fresh red cells, large macrophages, occasional polymorphonuclear leukocytes and eosinophilic granular material. Bronchioles showed severe epithelial degeneration and desquamation. Large areas of fresh hemorrhage were noted scattered throughout the parenchyma of the pancreas. Several foci of necrotic acinar tissue, the result of small infarctions, were seen, and bordering these areas were arteries with partial necrosis of their walls. The adrenal cortex was greatly increased in width because of hypertrophy and hyperplasia of the cells of the zona fasciculata and reticularis. The kidneys showed changes considered secondary to vascular disease. Medium-sized and small-sized arteries showed reduplication of the elastic lamella, hypertrophy and hyalinization of the mediums, and pronounced concentric intimal thickening and luminal narrowing. Many arteries were completely occluded by this process. Afferent and efferent arterioles were also decidedly hyalinized and narrow.

Glomerular pathologic changes reflected the two types of vascular disease, and about one half of the total number were completely hyalinized. Large numbers of other glomeruli were partly hyalinized, and varying fractions of the tuft were avascular. This change was considered secondary to chronic endarteritis. A few glomeruli showed acute thrombonecrotic lesions and acute glomerulitis consisting of proliferation of the cells of the capillary endothelium and of Bowman's capsule. Extensive atrophy of the tubules was present, and small areas of regeneration were also seen. The proximal convoluted tubules showed severe cloudy swelling and desquamation. The distal convoluted tubules and the collecting tubules showed severe widespread nuclear karyorrhexis and desquamation of the tubular epithelium. Many casts composed of cellular debris were present in the collecting tubules. The pathologic changes in the blood vessels and in the kidneys were considered compatible with the clinical diagnosis of a malignant phase of essential hypertension. The hemorrhage in the lungs was recent and probably terminal, and the pancreatic pathologic changes resulted from the acute thrombonecrotic arteritis.

### COMMENT

We believe that this death was directly attributable to the use of tetraethylammonium chloride. The sudden fall in blood pressure from excessively high to shock levels following injection of the drug could reasonably be attributed to no other cause. This toxic reaction was not dissimilar to the ones previously reported[6] in groups of patients with a comparably high diastolic pressure, except for its intensity, prolonged duration and fatal result. In as much as tetraethylammonium chloride is excreted almost quantitatively in the urine, 50 per cent appearing in the first thirty minutes, and this patient suffered from decided renal functional impairment, it is conceivable that the prolonged effect is due to diminished excretion of the drug. Postmortem observations did not reveal any coincidental pathologic change which might have been held responsible for the sudden vascular collapse. It is interesting that such a severe depressor reaction occurred in a patient who had had an extensive sympathetic resection.

### SUMMARY

A case in which death followed the intravenous injection of 500 mg. of tetraethylammonium chloride in a patient with malignant hypertension is presented. The danger of a severe toxic reaction to a patient in the malignant phase of essential hypertension is emphasized. The possibility that renal functional impairment may have prolonged the action of the drug is suggested.

## Council on Physical Medicine

*The Council on Physical Medicine has voted to adopt the following statement.* Howard A. Carter, *Secretary.*

### REBATES

Recently the Council on Physical Medicine adopted for publication the statement "Rebates" (The Journal, Oct. 30, 1948, p. 650). At its annual meeting on December 10, the Council expressed the opinion that such matters should be considered by the Judicial Council of the American Medical Association and voted to withdraw the statement. Therefore this statement is withdrawn.

### NEWER ADRENOLYTIC, SYMPATHOLYTIC, AND GANGLIONIC BLOCKING DRUGS

KEITH S. GRIMSON, M.D.
JAMES P. HENDRIX, M.D.
and
M. J. REARDON, M.D.
*Durham, N.C.*

Drugs capable of blocking vasoconstricting and blood pressure elevating effects of epinephrine have been known for many years. Early examples are ergotoxin, the Fourneau compound 933F and yohimbine. These drugs in higher dose range often depress sympathetic activity as judged by vasomotor reflexes. Other drugs such as ergotamine tartrate and 833F more potently depress or block sympathetic reflexes. In general usage these drugs are referred to as adrenolytic or sympatholytic compounds, since they block conduction along important efferent sympathetic nerve pathways. Properly an adrenolytic agent is one which nullifies an important effect of epinephrine, whereas a sympatholytic agent is one which nullifies sympathetic nerve transmission, usual reference being to adrenergic pathways controlling blood vessels and usual site of action being at the end organ. Although a sympatholytic drug by strict definition must be adrenolytic, the reverse is not necessarily true. Certain drugs may be adrenolytic only, since adrenolysis

---

6. Lyons, Hoebler, Neligh, Moe and Peet.[2] Lyons, Moe, Neligh, Campbell, Berry and Rennick.[3]

From the Department of Surgery and Medicine, Duke University School of Medicine.

uniformly requires less potency or a lower dose than that necessary for sympatholysis. Interruption of sympathetic nerve transmission may also be produced by other agents acting directly on ganglions without antagonizing epinephrine.

Although early experimental results with adrenolytic and sympatholytic drugs were promising, most compounds exhibited toxicity or produced undesirable side effects that discouraged clinical use. Currently, of this group, only 933F, piperidylmethyl benzodioxane, is receiving extensive clinical trial. It is used as an aid in the diagnosis of epinephrine-producing tumors (pheochromocytomas). Goldenberg, Snyder and Aranow[1] have worked out a dosage range in which the drug normally produces moderate elevation of blood pressure. Evidently a similar amount produces reduction of blood pressure if patients have hypertension associated with an adrenal tumor. This use is promising and evidently safe.

Extensive clinical trial of drugs with sympatholytic properties has developed recently using preparations such as "priscol" (2-benzyl-4, 5-imidazoline hydrochloride) and "dibenamine hydrochloride" (N,N-dibenzyl beta-chloroethylamine hydrochloride). These are adrenolytic and in sufficient dosage also block sympathetic vasoconstrictor pathways. They act peripherally and depress or block reflex vasopressor responses. Both have certain disadvantages. "Priscol" may produce side effects such as flushing of the skin, goose flesh, nausea, apprehension, palpitation and, in larger doses, disabling postural hypotension. Under continuing treatment these symptoms are usually mild and not seriously objectionable. "Priscol" may be given orally, intravenously, subcutaneously or intramuscularly. "Dibenamine" also may produce objectionable side effects including occasionally central toxic symptoms or confusion states. It is usually given intravenously. This disadvantage is offset, however, by prolonged action lasting for many hours to a day or two. Properties of "priscol" have been reviewed by Meier and Muller[2] and Ahlquist, Huggins and Woodbury.[3] Our group[4] has found "priscol" often valuable as a treatment for peripheral vascular disorders, particularly Raynaud's disease, traumatic or reflex vasospasm, and certain causalgias. The important properties of "dibenamine" have been reviewed by Nickerson and Goodman[5] and others. Clinical trial of these drugs has yielded only a little encouragement in the treatment of hypertension but has developed definite potential use as a substitute for regional sympathetic block or actual sympathectomy in peripheral vascular disease problems.

A third drug receiving extensive clinical trial differs from those cited above in that it acts as a generalized ganglionic blocking agent and is not adrenolytic. It belongs to a group of drugs which like nicotine and curare are able to block conduction through ganglions of the autonomic nervous system and may be referred to as ganglionic blocking agents. This drug, "etamon chloride" (tetraethylammonium chloride), although long known, only recently has been extensively studied and used clinically. Acheson and Moe[6] and their associates have thoroughly examined both pharmacologic and therapeutic actions. Its ganglionic blocking action is general and thus not only interrupts sympathetic impulses but also interferes with parasympathetic transmission, producing loss of accommodation, cessation or decrease of motility of the gastrointestinal tract and alteration of urinary bladder function. Its effects are promptly interrupted by administration of neostigmine.[7] Tetraethylammonium chloride may be given intravenously or intramuscularly. Favorable results of its use in vasospastic peripheral vascular disorders and causalgias are reported.

Marked temporary reduction of blood pressure can be produced by "priscol," "dibenamine" or tetraethylammonium chloride in patients with normal blood pressure or with hypertension. Partial obstruction of coronary or cerebral arteries is often present in patients with arterial hypertension or peripheral vascular disease. Occasionally, in patients of this type cerebral or myocardial ischemia has developed after reduction of blood pressure following drugs. Although not reported in the literature, deaths have occurred following use of tetraethylammonium chloride or "dibenamine" according to information made available to the authors. Therefore sympatholytic or ganglionic blocking drugs should be used with caution. Of the three drugs described reduction of blood pressure seems to be most easily avoided with "priscol," since a dose of 25 to 50 mg. every three or four hours permits dilation of blood vessels of the extremity without significant reduction of blood pressure. The dose range required for an appreciable fall of pressure with this drug is 75 to 200 mg. Reduction of blood pressure caused by "dibenamine" or "priscol" can be counteracted by administration of posterior pituitary but not by neostigmine.

These drugs have been reported useful in a variety of clinical conditions, including Raynaud's disease, arteriosclerotic obstructive vascular disease, thromboangiitis obliterans, causalgias, phlebothrombosis or thrombophlebitis, acute ischemia, livedo reticularis, acrocyanosis, trench and immersion foot, lymphedema, post-traumatic edema, frostbite, scleroderma, postherpetic neuralgia and hypertension. Nevertheless, each of the drugs has limitations and, although valuable for certain of these clinical problems and useful as research tools, they have not yet received the widespread clinical trial necessary for them to qualify as standard therapeutic agents. Qualification will depend on proper use in well selected patients who are closely observed by their physicians. Although promiscuous use of these drugs might be dangerous, reports of extensive and careful clinical trial would indicate that judicious employment for the present may be encouraged. It is hoped that some of the numerous adrenolytic, sympatholytic or ganglionic blocking preparations now being developed may permit extension of advantages and decrease of side effects.

## NEW AND NONOFFICIAL REMEDIES

*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

Austin Smith, M.D., *Secretary.*

**POISON IVY-POISON OAK EXTRACT COMBINED.—Ivoko-Pitman-Moore.**—A combination of equal parts of the extracted solids of the dried leaves of poison ivy and oak prepared in accordance with requirements of the National Institute of Health.

*Actions and Uses.*—Poison Ivy-Poison Oak Extract Combined is used for the prevention of symptoms of dermatitis due to contact with either of these plants.

*Dosage.*—Parenteral injections of the number and volume recommended for the product used. The interval between doses is usually two weeks.

An extract standardized to contain 1 mg. of total extracted solids (0.5 mg. of each) per cubic centimeter is administered in an average dose of 0.1 cc. of the extract diluted to a volume of 1 cc. In hypersensitive persons, one twentieth of that dose should be used as a test dose and the dose then gradually increased to the average. It is administered at intervals of one to three weeks during exposure.

Pitman-Moore Company

**Ivoko Poison Ivy-Poison Oak Extract with Sterile Diluent:** 1 mg. extracted solids per cc., 1 cc. vials each packaged with six 0.9 cc. vials of 0.5 per cent procaine hydrochloride in isotonic sodium chloride solution. Preserved with chlorobutanol 0.4 per cent as a sterile diluent.

SATURDAY, JANUARY 15, 1949

## THE DRIFT TOWARD A SOCIALIST DEMOCRACY

The consensus of editorial writers whose opinions have become available on the address given by President Truman to the Congress on January 5 indicates their point of view that the President is considerably left of what used to be called the New Deal. The Congress, if it should adopt any considerable number of the recommendations made, would move the nation away from its present status as a republic or a true democracy into a condition which resembles what is called in Europe a socialist democracy. Adhering to the pattern followed by other nations in this drift, President Truman said:

> We must spare no effort to raise the general level of health in this country. In a nation as rich as ours it is a shocking fact that tens of millions lack adequate medical care. We are short of doctors, hospitals and nurses. We must remedy these shortages. Moreover we need, and we must have without further delay, a system of prepaid medical insurance which will enable every American to afford good medical care.

A careful analysis of the statement quoted indicates the necessity for an absolute denial of the statement made that "tens of millions lack adequate medical care." Such statements should not be made without the ability to produce the evidence in their support. As far as can be determined by all available studies, and particularly recent studies, that statement is not supported by competent evidence.

The President says that we are short of doctors, hospitals and nurses. Actually the United States, as was proved in a statement published in these columns recently, has more doctors in proportion to the population than any other country in the world, whether with or without a system of socialized medicine. True, there are faults of distribution of physicians which need to be remedied. The faults, however, are related to economic rather than other factors. The Congress has passed and the government has implemented the Hill-Burton Act for increasing hospitals about as rapidly as they can be increased. The chief difficulty at present is the difficulty of finding personnel to staff such hospitals and the economic conditions sufficient to support such hospitals.

The American Nurses' Association, the American Red Cross, the American Surgical Association, the American College of Surgeons, the American Medical Association and, in fact, all organizations in this country interested in the utilization of nurses have been working on technics for increasing the available supply of nurses, and enrolments were 5,000 more in 1948 than in 1947; the total answer is not yet apparent. If the federal government or any of its agencies has an answer to the problem of the nurse supply, that answer will be welcomed by the medical profession. Many of the nurses themselves insist that it is simply a question of adequate remuneration in comparison with what other employees, particularly those affiliated with unions, are paid for their services.

The final sentence of Mr. Truman's recommendation brings some interesting thoughts. The first time he uses the words "adequate medical care" and the second time "good medical care," whereas Mr. Ewing usually says "proper medical care." What is needed at this time is a definition by some appropriate agency of these terms "adequate," "good" and "proper." There is plenty of evidence that the kind of medical care given in other countries under such systems as that proposed for the United States has no resemblance to the quality of medical service that now prevails in the United States. When diagnosis is made on the basis of one or two questions and when therapy is provided on the same basis, when doctors try to see from 40 to 100 patients a day in order to give the kind of medical care that can be given under such circumstances—and that is the case in many of the countries that have these systems—the medical care cannot be characterized as "adequate," "good" or "proper." Apparently what the proponents need is some adequate, good or proper term to characterize the kind of medical care that they refer to. The medical profession contends that it is inadequate, bad and improper. The one positive characteristic that it has is the fact that it is provided by the government following taxation of all of the workers of the country; a proper term would be nationalized, bureaucratic, governmental or socialized medical care.

Following the address by President Truman, a bill was introduced into the Senate bearing the names of Senators Murray, McGrath, Wagner, Chavez, Taylor and Pepper and into the House of Representatives by Congressman Dingell, which assurance from Senator Murray's office indicates is identical with Senate Bill 1320 except for the change in date and a new number, which is Senate Bill 5. As far as can be determined, there is no cry for this type of government medical service from the vast majority of the middle class people of the United States. Ours apparently is the only nation in the world still possessing a large middle class. Nor is there any insistent demand for this legislation from rural groups. In the meantime, moreover, statements just made available from competent sources indicate that at the present time 52,000,000 Americans are insured against the costs of hospitalization, 31,000,000 against loss of income due to disability, 26,000,000 against surgical expense and 9,000,000 against medical expense. This is the most rapid rate of growth of any form of prepaid medical insurance on a voluntary basis that the world has ever known. It answers the President's request—but it is not compulsory!

## ARMED FORCES MEDICAL ADVISORY COMMITTEE

As was announced to the House of Delegates at the St. Louis Session and as reported by our Washington correspondent, Secretary of Defense James Forrestal on December 13 appointed an Armed Forces Medical Advisory Committee which included nine civilian leaders of the medical profession, the Surgeons General of the Army and Navy and the Air Surgeon. At the same time Secretary Forrestal announced that Mr. Charles Proctor Cooper, president of the Board of Trustees of the Presbyterian Hospital in New York City, had accepted appointment to act as his deputy for all medical matters affecting the armed forces. He will also serve as chairman of the Armed Forces Medical Advisory Committee. The members of the committee are:

Dr. Raymond B. Allen, Seattle, President of the University of Washington
Dr. Edward D. Churchill, Boston, Professor of Surgery, Harvard Medical School, and formerly President of the American College of Surgeons
Dr. Michael DeBakey, Professor of Surgery, Baylor Medical College, Houston, Texas
Dr. Paul R. Hawley, Chicago, formerly Chief Medical Director, Veterans Administration
Dr. Richard D. Meiling, Assistant Professor of Obstetrics and Gynecology, School of Medicine, Ohio State University, Columbus, Ohio
Dr. Maurice C. Pincoffs, Professor of Medicine, University of Maryland, Baltimore
Dr. Howard A. Rusk, Professor and Chairman of the Department of Rehabilitation and Physical Medicine, New York University College of Medicine, and Medical Editor, *New York Times*
Dr. Walter H. Scherer, Houston, Texas, Past President, American Dental Association
Dr. Paul Titus, Pittsburgh, Secretary-Treasurer and Director American Board of Obstetrics and Gynecology
Maj. Gen. Raymond W. Bliss, M.C., U.S.A., Surgeon General of the Army
Rear Admiral Clifford A. Swanson, M.C., U.S.N., Surgeon General of the Navy and Chief of the Bureau of Medicine and Surgery
Maj. Gen. Malcolm C. Grow, M.C., U.S.A., The Air Surgeon

This committee will submit recommendations on general policies on the development of medical and allied services, on the elimination of unnecessary duplications or overlapping in the medical departments and the development of complete cooperation between the physicians of the armed forces and the civilian medical profession. By action of Mr. Forrestal, this committee will also give advice or assistance, on request, to the secretaries of the Army, the Navy and the Air Force, the chairman of the Munitions Board and the Research and Development Board. This committee succeeds the committee formerly known as the Hawley Board, which was established to study and recommend concerning improvements in the medical organizations of the national military establishment.

Thus comes fruition to a proposal of the Committee on National Emergency Medical Service of the American Medical Association, of which Dr. James B. Sargent is chairman. This committee has urged repeatedly the establishment of such a body as the one created by Secretary Forrestal as being vital to economical use of medical personnel and to meeting the needs of both the armed forces and the civilians of our country in times of emergency. No doubt the committee will, following its organization, establish an executive group which can assemble at least once each month in order to be aware of current problems and to act promptly.

## AMERICAN PUBLIC HEALTH ASSOCIATION RESOLUTIONS

On page 159 of this issue appear two resolutions adopted at the annual meeting, held in Boston in November 1948, of the American Public Health Association.

One resolution deals with cooperation in the school health program and calls on the National Education Association and the American Medical Association to cooperate with the American Public Health Association and other groups in approving the principle of cooperative planning of health programs which involve children of school age. This resolution expresses the long declared and well implemented policy of the American Medical Association which began with the first meeting of the Association in 1847 and has been continuously a guiding principle in its policy. Since 1911, the American Medical Association and the National Education Association have cooperated through a Joint Committee on Health Problems in Education. Frequent symposiums on health of school children have been held at American Medical Association meetings. The Association has an active program of cooperation with educational agencies for better national health achieved through better health education and school health programs.

The second resolution likewise coincides with the views of physicians often expressed, that the present system of allotting state aid to schools and school districts in part on the basis of average daily attendance is pernicious, conducive to attendance by children who are harming themselves and menacing others and a temptation to the violation of sound sanitary principles for the school in increasing or maintaining subsidies.

The nation's leading public health organization does well to invite cooperation of the medical profession. Successful public health workers in official and voluntary agencies have long since learned that a cooperative medical profession is their strongest and best ally, but this idea has not seemed to permeate to certain leaders of the public health profession.

The two resolutions calling on the American Medical Association for cooperation represent but two in the many areas of agreement between the associations. Others include the movement for county health unit coverage, the fight for universal pasteurization, the better training of public health personnel with a consequent improvement in salaries and tenure, the extension of the merit system in public health official agencies, the advance of medical research and the perennial battle against quackery. The organizations representing the medical profession and the public health profession should face the public united in their areas of agreement, especially since there is a large overlapping in membership.

## COMBINED STREPTOMYCIN-POTASSIUM IODIDE THERAPY

Iodides cause tubercle bacilli to appear in the sputum of patients with pulmonary tuberculosis. Jobling and Petersen[1] showed that iodine neutralizes the ferment-inhibiting properties of unsaturated fatty acids in caseous materials, thus releasing fermentation or autolysis. This causes a liberation of the bacilli and their appearance in the sputum. Jobling thought that the same autolytic process might serve a useful purpose by facilitating solution and absorption of caseous matter in other parts of the body and might thus expose masked tubercle bacilli to the influence of chemotherapeutic agents.

In the light of this significant suggestion and in view of the relatively poor results obtained in the treatment of fibrocaseous tuberculosis with streptomycin alone,[2] Woody and Avery[3] of the Department of Pathology, Vanderbilt University, tested the combined effect of potassium iodide and streptomycin against established tuberculosis in guinea pigs.

Forty-six young guinea pigs ranging in weight from 350 to 450 Gm. were inoculated in the groin with 0.3 mg. of virulent tubercle bacilli (H37RV). Treatment was delayed till the end of the fourth week. Fifteen of the guinea pigs were then set aside to serve as untreated controls. Fifteen were given daily intramuscular injections of 37,500 micrograms streptomycin per kilogram of body weight, given in fractional doses at six hour intervals.

The remaining 16 guinea pigs were given the same doses of streptomycin plus 80 mg. potassium iodide daily by stomach tube. Treatment of both groups was continued for five weeks. Three weeks later, or at the end of the twelfth week of the infection, 13 of the 15 untreated controls were dead and 5 of the 15 streptomycin-treated guinea pigs had died, while only 1 of the 16 treated with streptomycin and potassium iodide had succumbed. Two animals of each group were then killed for histologic study. By the end of fifteen weeks, deaths from tuberculosis were: controls, 13 of 13 animals; streptomycin group, 6 of 13 animals, and streptomycin–potassium iodide group, 2 of 14.

In earlier groups all animals were killed at the end of four weeks of treatment. On gross examination the untreated controls and a group given only potassium iodide showed heavy tuberculous infection of all viscera. In the streptomycin-treated group, but 5 of the 10 guinea pigs showed a mild spread of tuberculosis to the internal organs. In the group treated with streptomycin and potassium iodide the internal organs were free from macroscopically demonstrable tuberculosis.

The results of these tests were so encouraging that combined streptomycin–potassium iodide therapy is now being tried with tuberculous patients.

# Current Comment

## EXTREME SALT EXCRETION

One of the inherent problems of the mammalian organisms is the conservation of water. The kidney excretes as little water as possible but as much as necessary to eliminate in solution the cellular metabolites. When the need for heat loss is minimal the skin likewise behaves like an integument designed to retain water, and the fluid loss through the intestines is ordinarily depressed by the effective absorption in the large intestine. This tendency for water retention is exaggerated in the kangaroo rat and the pocket mouse, two desert mammals whose renal excretion of salts has recently been studied.[1] The experimental animals were given dry grain without water for six weeks, after which the same grain (rolled barley) containing about 10 per cent sodium chloride was fed. They gained weight on the dry grain alone but lost weight when salt was added to the diet. The survival time of the kangaroo rats maintained on the salt-containing ration was about a week but, even then, the water content of the body tissues was not depressed. As much as 0.908 normal chloride was excreted in the urine on the salt diet period, which is one and one-half times the normal maximum for the laboratory rat, almost three times that of man, dog or goat. These data provide evidence of extraordinary effectiveness of the kidney in eliminating salts with minimal loss of water under extreme conditions of stress. Whether or not the usual pattern of exchange in the tubules is maintained under the foregoing experimental conditions should be determined.

# ORGANIZATION SECTION

## *Official Notes*

### RESOLUTIONS BY THE AMERICAN PUBLIC HEALTH ASSOCIATION

The Governing Council of the American Public Health Association, at its Seventy-Sixth Annual Meeting, Boston, Nov. 10, 1948, adopted the following resolutions:

1. WHEREAS, The American Public Health Association is concerned with the health of the total community; and

WHEREAS, It has become increasingly clear that the school health program can contribute significantly to the over-all public health program; and

WHEREAS, Both education and health departments have great interest in the health of the school age child; and

WHEREAS, It is becoming increasingly apparent that where there is a high degree of mutual understanding and cooperation between departments of health and education, with the resultant pooling of the resources of both departments, good school health programs are being developed; therefore be it

*Resolved*, That the American Public Health Association join with the National Education Association and the American Medical Association and other groups in approving the principle of cooperative planning of health programs which involve children of school age.

2. WHEREAS, The allocation of the moneys to schools and school districts is based on a variety of formulas, among which is the classroom unit as computed by average daily attendance; and

WHEREAS, If funds are allotted on the basis of average daily attendance, school officials find it to their advantage strongly to promote daily attendance of all children at school; and

WHEREAS, The encouragement of children to attend school when they are ill has deleterious effects on the health of individual children and may be responsible for the spread of communicable diseases; therefore be it

*Resolved*, That the American Public Health Association join with the National Education Association, the American Medical Association and other groups in decrying this practice, and be it further

*Resolved*, That the National Council of State School Officers and the Association of State and Territorial Health Officers be urged to develop a plan of allotting tax moneys for educational purposes in a way that is not deleterious to the health of children.

## *Washington Letter*

*(From a Special Correspondent)*

Jan. 10, 1949.

### Labor Press Intensifies Health Insurance Campaign

The turn of the year witnessed intensification of organized labor's crusade for enactment of compulsory sickness insurance by the Eighty-First Congress, as manifested by articles, editorials and cartoons in union newspapers. The January 6 issue of *The Machinist*, which claims a circulation of 2,000,000, carried a "coupon" purporting to refute arguments against nationalization and urging union members to clip it out and "mail it or take it with you next time you go to see your family physician." An accompanying article charged that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION refuses to publish anything favorable to health insurance.

*Trainman News*, official weekly of the Brotherhood of Railroad Trainmen and with an announced readership of 500,000, criticizes the special assessment voted by the American Medical Association House of Delegates and otherwise repeats stock criticism of the medical profession as supplied by the Committee for the Nation's Health. Incidentally, the "coupon" published in *The Machinist* invites physicians to write to the Committee for the Nation's Health literature supporting compulsory insurance. *CIO News*, in its final issue of 1948, reprinted an editorial from the *St. Louis Post-Dispatch* which expresses skepticism of the adequacy of voluntary prepayment plans.

### Three New Senators Watched on Health Legislation

Among the new Senators who were sworn in when the new Congress convened January 3, three in particular are expected to take prominent roles in consideration of prospective legislation on national health and social welfare. They are Hubert H. Humphrey of Minnesota, Paul H. Douglas of Illinois and Dr. Lester C. Hunt of Wyoming. All are Democrats and all were supported, in their campaigns, by organized labor. Dr. Hunt is the Senate's only dentist member (there are no physicians in that body). Humphrey, who holds a pharmacy degree, placed great emphasis on public health when he was mayor of Minneapolis. Another new Democrat member, Joseph Allen Frear Jr., of Delaware, is a member of the American Hospital Association and president of the Kent General Hospital Board in his home town of Dover, Del.

### Transfer of Veterans Hospitals Opposed by American Legion

The American Legion will fight transfer of the Veterans Administration medical department—including its 126 hospitals—to a "National Bureau of Health" as recommended by a Hoover Commission "task force." T. O. Kraabel, national rehabilitation director of the Legion, with offices in Washington, stated:

"The Legion holds that medical and hospital services of the best quality are essential not only to adequate identification and treatment of diseases but also as to exhaustive and correct descriptions for purposes of adjudicating veterans claims. This cannot be satisfactorily accomplished if medical and hospital services are separated from the administrative setup. . . . At present there are over 2,000,000 veterans of all wars suffering from service-incurred or aggravated disabilities. Total disability cases filed exeed 6,000,000. The American Legion supports the present VA hospital system and construction program as essential to meet future needs in respect to caring for these veterans. The Legion will vigorously oppose any action that will spell the disintegration or absorption of the Veterans Administration and the dilution or the devitalizing of the present program of the best possible medical and hospital care for veterans."

### Dr. Magnuson May Resign if Not Given Free Hand

Dr. Paul B. Magnuson, chief medical director of the Veterans Administration, has made it clear that he will resign rather than compromise principles of professional standards in operation of Veterans Administration's large medical and hospitalization program. On his return to Washington from a ten day inspection trip, he confirmed reports that pressure is being exerted within the Veterans Administration to effect certain changes, particularly in reference to location of hospitals. "There's likely to be a hell of a fight in the next few weeks to decide who's running this department," he declared. "I think I am," he added. Meanwhile, Dr. Magnuson announced establishment of the Veterans Administration's eleventh radioisotope diagnostic and treatment unit at the Nashville (Tenn.) Veterans Hospital. The newest facility for application of atomic medicine will be conducted in close cooperation with Vanderbilt University School of Medicine and the Nashville Deans Committee.

### Oak Ridge Institute Opened to Foreign Medical Researchers

Atomic Energy Commission has announced opening of radioisotope training facilities at Oak Ridge Institute of Nuclear Studies to a limited number of foreign scientists. First to take advantage of the plan are Dr. K. Aterman, of the department of anatomy, University of Birmingham (England), and P. S. Krishnan, of Madras, India, who has been a research associate in enzyme chemistry at Cornell University since he received his Ph.D. in biochemistry at that institution in 1947. Dr. Aterman came to this country for postgraduate study at Harvard Medical School on a Commonwealth Fund fellowship. The two scholars are members of the special class in technics of using radioisotopes in research that opened at Oak Ridge January 3. The course is one month in length.

# Medical Legislation

## STATE LEGISLATION

The legislature of the following states will meet in regular session during 1949.

| State | Convenes | Time Limit |
|---|---|---|
| Alabama | May 3 | 36 days |
| Arizona | Jan. 10 | 60 days |
| *Arkansas* | *Jan. 10* | *60 days* |
| California | Jan. 3 | None |
| Colorado | Jan. 5 | None |
| Connecticut | Jan. 5 | June 8 |
| Delaware | Jan. 4 | 60 days |
| Florida | Apr. 5 | 60 days |
| Georgia | Jan. 10 | 70 days |
| Idaho | Jan. 3 | 60 days |
| Illinois | Jan. 5 | None |
| Indiana | Jan. 6 | 61 days |
| Iowa | Jan. 10 | None |
| Kansas | Jan. 11 | 60 days |
| Maine | Jan. 5 | None |
| Maryland | Jan. 5 | 90 days |
| Massachusetts | Jan. 5 | None |
| Michigan | Jan. 5 | None |
| Minnesota | Jan. 4 | 90 days |
| Missouri | Jan. 5 | None |
| Montana | Jan. 3 | 60 days |
| Nebraska | Jan. 4 | None |
| Nevada | Jan. 17 | 60 days |
| New Hampshire | Jan. 5 | None |
| New Jersey | Jan. 11 | None |
| New Mexico | *Jan. 11* | *60 days* |
| New York | Jan. 5 | None |
| North Carolina | Jan. 5 | None |
| North Dakota | Jan. 4 | 60 days |
| Ohio | Jan. 3 | None |
| Oklahoma | Jan. 4 | 75 days |
| Oregon | Jan. 10 | 50 days |
| Pennsylvania | Jan. 4 | None |
| Rhode Island | Jan. 4 | 60 days |
| South Carolina | Jan. 11 | 40 days |
| South Dakota | Jan. 4 | 60 days |
| Tennessee | Jan. 3 | 75 days |
| Texas | Jan. 11 | 120 days |
| Utah | Jan. 10 | 60 days |
| Vermont | Jan. 5 | None |
| Washington | Jan. 10 | 60 days |
| West Virginia | Jan. 12 | 60 days |
| Wisconsin | Jan. 12 | None |
| Wyoming | Jan. 11 | 40 days |

### Massachusetts

**Bills Introduced.**—H. 167 proposes the enactment of a **voluntary system** for the payment of hospital, surgical operation, sickness, bodily injury and maternity benefits to employees. H. 261 proposes to amend the existing law so as to declare nonprofit hospital service corporations, medical service corporations and nonprofit medical service plans to be **charitable corporations.** H. 319 proposes the enactment of a **cash sickness compensation** act. H. 365 proposes that any veteran of World War II who graduated from any medical school on or before June 1948, and who served an internship of not less than one year in an approved Massachusetts hospital and was a resident of Massachusetts shall be entitled to take the **examination for a license** to practice medicine in the state. H. 440, to amend the law *relative* to **physical examination of school children,** proposes that tests of sight and hearing of school children shall be made by qualified physicians. H. 494, to amend the workmen's compensation act, proposes that the *record of the* ***history,*** *examination, diagnosis, prognosis* or *treatment* **of an employee** shall not be furnished, nor shall any of the information contained therein be furnished or disclosed, to any employer or insurer or to his or its agents, servants or attorneys by any doctor, physician, surgeon, nurse or other person who shall examine, treat or attend such employee unless the employee consents thereto in writing prior to such furnishing or disclosure. H. 499 and H. 915 to amend the workmen's compensation act, propose that physicians called as expert witnesses in workmen's compensation hearings shall be allowed **a reasonable fee** by the department for testifying and that such fee shall include reasonable amounts for examinations, diagnostic studies and reports as well as appearances and testimony and shall in no case be less than $35. H. 507, to amend the *workmen's compensation* act, proposes that impartial ***examinations prior to a hearing*** *shall be* granted only at the request of the employee, or following a hearing, in the discretion of the department or any member thereof, after opportunity for the employee to object to the impartiality of the physician and to present evidence thereon. H. 589, H. 590 and H. 1003, to amend the law relating to **the sale of cosmetics,** propose that no person other than a licensed hairdresser shall sell or offer for sale at retail, or dispense or give away any cosmetic containing any harmful chemical. Harmful chemical is defined to include ammonium hydroxide, thioglycolic acid and formaldehyde. H. 592 proposes that any duly registered physician licensed to practice medicine and surgery in the state shall be entitled to treat his or her patients in any public or semipublic hospital, that **no physician shall be discriminated against** or refused the right of practicing his profession in any public hospital because he is not a member of the Massachusetts Medical Society and that no physician shall be denied the use of such hospital because of his religion, nationality, race or sex. H. 733, H. 1138 and H. 1475 are comprehensive proposals for the licensing and regulating *of persons and institutions desiring to engage in* **animal experimentation** upon live animals. H. 851 proposes, among other things, that the trustees of the University of Massachusetts shall establish and maintain **two medical schools,** one to be located in the eastern part and the other in the western part of the state. H. 913, to amend the workmen's compensation act, proposes that any physician who has **testified either for an insurer or a claimant at least three times** in the preceding twelve months, shall not be eligible to be appointed by the compensation commissioner as an impartial physician. H. 1000 proposes that all persons engaged in the **preparation of food for human consumption** shall be required to undergo annually physical examinations by reputable *practicing physicians* in the *employment of the* state department of public health and shall be required as a condition to continuing work *to* be certified *by* such examining physicians to be *free from any and all communicable diseases or diseases endangering* the public health. H. 1010 proposes conditions under which graduates of the College of Physicians and Surgeons who received the degree of doctor of medicine prior to January 16, 1947 may be admitted to **examination for medical licensure** in the state. H. 1011 proposes that *any person who is a resident of the commonwealth and who matriculated* at any medical school in the commonwealth beginning with January 1913, may, under certain circumstances, be admitted to examination for **medical licensure in the state.** This proposal apparently is also for the benefit of graduates of the College of Physicians and Surgeons. H. 1446 proposes to require **owners or managers of restaurants** to display a certificate for each employee showing such employee to be free from communicable disease. H. 1530, to amend the law *relative to the making* ***of tests of sight of school children,*** proposes that *the tests of sight shall be made by the teachers or registered optometrists,* tests of hearing shall be made by the teachers, and examinations of feet shall be *made by* the school physicians. H. 1875 proposes that the sale of any drug, medicine, instrument or article whatever, one result of the use of which is or may be **the prevention of conception,** shall be presumed to have been made in violation of the law relative to criminal sales. S. 182 proposes that **a registered physician or surgeon or osteopath** shall not, without the consent of his patient, be examined in a civil or criminal action as to any information acquired in attending such patient which was necessary to enable him to prescribe or act for his patient. S. 266 proposes that whoever experiments or **operates** in any manner whatsoever **upon any living dog or cat** for any purpose other than the healing, curing or sterilizing of said dog or cat shall be punished by fine or imprisonment or both. S. 404 proposes the creation of a special commission to make a survey and study of the subject of **spastic paralysis.** S. 463 proposes the creation of a board of **examiners of chiropractic** and proposes to define chiropractic as "The science of restoring the proper neuro-muscular dynamic relationship along the spinal column by the correction of misalignment or subluxations of the vertebral column, such restoration and correction being made by hand adjustment only. The practice of chiropractic shall not include operative surgery, prescription or use of drugs or medicine, or the practice of obstetrics, except that in such practice the x-ray may be used solely for the purpoe of examination."

### North Dakota

**Bills Introduced.**—H. 41 proposes to authorize a court to appoint **expert witnesses** in any proceeding when the court deems such expert testimony desirable. S. 28 proposes to require every physician or other person **authorized by law to practice obstetrics** who attends a pregnant woman in North Dakota for conditions relating to pregnancy during the period of gestation or at delivery to take or cause to be taken a sample of blood of such woman at the time of the first professional visit or within ten days thereafter and to submit such sample to an approved laboratory for a standard serologic test for syphilis.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

International Post-Graduate Medical Assembly of Southwest Texas, San Antonio, Jan. 25-27. Dr. John J. Hinchey, P. O. Box 2445, San Antonio, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Southeastern Allergy Association, Durham, N. C., Washington-Duke Hotel, Jan. 22-23. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia, S. C., Secretary.

Southeastern Surgical Congress, Biloxi, Miss., Jan. 24-27. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Ga., Secretary.

Western Section American Urological Association, Coronado, Calif., Hotel del Coronado, Jan. 17-19. Dr. Adolph A. Kutzmann, 1930 Wilshire Blvd., Los Angeles 5, Secretary.

# GOVERNMENT SERVICES

## ARMY

### CAMPAIGN TO MEET URGENT MEDICAL MAN POWER REQUIREMENTS

The Surgeon General has announced a program to unite professional and civic support in every community behind a campaign to meet urgent man power requirements of the Army Medical Department through volunteers. The program involves setting up professional man power committees in communities and coordinating them with the existing military man power committees which are already helping the general recruiting campaign. The medical program is part of the drive to obtain physicians, dentists, nurses and other medical specialists to meet the needs for medical care of the services.

The Selective Service Act provides that "no person shall be inducted until adequate provision shall have been made for medical care." To date, the medical departments are meeting their obligation to provide adequate medical care to men coming into the service. But as the physicians and dentists now on duty finish their service and are separated, others must be obtained to replace them. This shortage of medical personnel, if it continues, is viewed as a serious threat to national defense. The new program is an effort to obtain enough volunteers to meet the need.

The program was worked out by the Army Medical Department in cooperation with the Army and Air Force Recruiting Service. In communities, outstanding physicians, surgeons, dentists and other leading medical specialists will be asked to serve on professional man power committees, which will be set up as subcommittees to the military man power committees which are already assisting the recruiting service. The cooperation of existing Army advisory committees also will be sought, particularly in the larger cities.

The plan for civilian aid to medical personnel procurement has been developed in consultation with the national societies representing the professional fields involved. It will seek the help of local units of professional organizations and enlist the cooperation of local chapters of veteran, civic and fraternal groups which have been helping the services in their recruiting campaigns. The Army Medical Department will maintain liaison with national professional societies and associations to coordinate procurement programs and national organization policy. National advertising and publicity will be used to focus public attention on achievements and opportunities in the medical departments of the services.

### CIVILIAN RESIDENCY AND INTERN PROGRAMS

Applications for participation in the civilian residency and the civilian intern training programs by physicians will be accepted by the Army Medical Department beginning immediately. The two programs permit the further training of six hundred physicians under the sponsorship of the Army Medical Department.

The civilian residency training program permits the commissioning in the Regular Army of three hundred selected graduates of medical schools approved by the American Medical Association, who have satisfactorily completed an acceptable internship and have been accepted for a residency at an approved institution. Applicants accepted by a Board of Medical Department Officers will be given an opportunity to serve a residency of their own choice in any civilian hospital approved by the American Medical Association. Physicians selected to participate in the civilian residency program will be commissioned as first lieutenants or captains. In addition to the regular pay and allowances of their grades, the physicians will receive $100 per month which has been authorized for volunteer Army medical officers.

Selection of applicants for residencies will be completed by April 1. The civilian residency program for the fiscal year 1950 will get under way in July. This program has been established to provide specialty training to physicians interested in a career in Army medicine. All physicians accepting civilian residencies will be required to serve one year on active duty for each year of formal training received.

The civilian intern training program also permits the selection of three hundred candidates for participation. Training will be open to selected potential medical school graduates who plan to begin internship between Jan. 1 and July 1. The applicants must fulfil the requirements necessary for appointment as first lieutenants in the medical corps reserve and must have been accepted for internship training in a civilian hospital approved by the American Medical Association. Candidates selected to participate in the civilian intern training program will complete their internships as officers on active duty with full pay and allowances in the grade of first lieutenant. Physicians receiving training under this program will be required to serve one year on duty status as officers in the Regular Army Medical Corps for each year of formal training received.

Physicians interested in either the civilian residency program or the civilian intern training program can procure application forms from the Surgeon General, Attention: Chief, Procurement Branch, Personnel Division, Washington, D. C.

### CONSULTANTS TO THE EUROPEAN COMMAND IN 1948

The Surgeon General's Office has been carrying out a program designed to bring to the Army Medical Department in the European Area the latest advances in the field of medicine and in so doing assigned during 1948 the following civilian consultants to aid in this work:

| Name | Residence | Specialty |
|---|---|---|
| | JANUARY | |
| Finney, George | Eccleston, Md. | Surgery |
| Martin, Walter B. | Attica, N. Y. | Medicine |
| Smith, Beverly, Col. | Washington, D. C. | Neuropsychiatry |
| | FEBRUARY | |
| Bost, Frederic C. | San Francisco | Orthopedics |
| Marble, Alexander | Boston | Medicine |
| Rosenberg, Seymour J. | Washington, D. C. | Neuropsychiatry |
| | MARCH | |
| Balser, Benjamin H. | New Rochelle, N. Y. | Neuropsychiatry |
| Gordon, Burgess | Philadelphia | Medicine |
| Hamilton, Frank E., Col. | Washington, D. C. | Surgery |
| Scheie, Harold | Philadelphia | Ophthalmology |
| | APRIL | |
| Bruton, Ogden C., Lieut. Col. | Washington, D. C. | Pediatrics |
| Lady, William T. | Washington, D. C. | Obstetrics & Gynecology |
| Walsh, Maurice N. | Rochester, Minn. | Neuropsychiatry |
| Wells, Warner L. | Raleigh, N. C. | Surgery |
| | MAY | |
| Cope, Oliver | Boston | Surgery |
| Curtis, Arthur C. | Ann Arbor, Mich. | Medicine |
| Hoagland, Tomas V. | Detroit | Neuropsychiatry |
| Soto-Hall, Ralph | San Francisco | Orthopedics |
| | JUNE | |
| Duncan, Garfield G. | Philadelphia | Medicine |
| French, A. James | Ann Arbor, Mich. | Pathologist |
| Leonard Thomas M. | Washington, D. C. | Obstetrics & Gynecology |
| Margolin, Sydney G. | New York | Neuropsychiatry |
| Stiefel, Richard A. | Battle Creek, Mich. | Surgery |
| | JULY | |
| Beecher, Henry K. | Boston | Anesthesia |
| Godard, C. H. | Pasadena, Calif. | Neuropsychiatry |
| Greear, James N. | Washington, D. C. | Ophthalmology |
| Leedham, Charles, Col. | Augusta, Ga. | Medicine |
| Porter, William B. | Richmond, Va. | Medicine |
| | AUGUST | |
| Berlien, Ivan C. | Detroit | Neuropsychiatry |
| Hixson, Clayton | Washington, D. C. | Obstetrics |
| Shull, Harrison J. | Nashville, Tenn. | Medicine |
| Stark, Jessee D. | New York | Radiology |
| | SEPTEMBER | |
| Ambler, John V. | Denver | Medicine |
| Barr, David | New York | Medicine |
| Daniels, Luman E. | Denver | Neuropsychiatry |
| Hart, Vernon L. | Minneapolis | Orthopedics |
| | OCTOBER | |
| Haden, Russell L. | Crozet, Va. | Medicine |
| Stewart, George A. | Baltimore | Surgery |
| Talkington, Perry C. | Dallas, Texas | Neuropsychiatry |
| Thomas, Atha | Denver | Orthopedics |
| | NOVEMBER | |
| Hench, Philip S. | Rochester, Minn. | Medicine |
| Kern, Richard A. | Philadelphia | Medicine |
| Tobin, William J. | Washington, D. C. | Orthopedics |

# NAVY

## FIRST ACTIVE DUTY AS INTERNS

The following lieutenants (jg) in the Medical Corps Reserve have reported for their first active duty as interns under the Navy Medical Training Program at the institutions indicated:

| Name | Residence | Destination |
|---|---|---|
| Allen, Alan W. | Santa Monica, Calif. | Santa Monica Hospital, Santa Monica, Calif. |
| Andrews, William J. | Oak Park, Ill. | Cook County Hospital, Chicago |
| Beasom, Ralph D. | Glendale, Calif. | California Lutheran Hospital, Los Angeles |
| Benedict, Paul F. | Vevay, Ind. | Indiana University Medical Center, Indianapolis |
| Bianco, Anthony J., Jr. | West Duluth, Minn. | St. Mary's Hospital, Duluth |
| Brady, Luther W. Jr. | Bethesda, Md. | Jefferson Hospital, Philadelphia |
| Brown, Crawford S. | Washington, D. C. | Germantown Hospital, Philadelphia |
| Burke, Donald R., Jr. | Seattle | King County Hospital, Seattle |
| Egge, Robert K. | Maplewood, N. J. | Newark City Hospital, Newark |
| Fyler, Donald C. | Silver Spring, Md. | Bellevue Hospital, New York |
| Gallagher, Raymond C. | San Jose, Calif. | Highland-Alameda County Hospital, Oakland, Calif. |
| Gill, Robert J. | Philadelphia | Pennsylvania Hospital, Philadelphia |
| Gilpin, Clifford R. | Evanston, Ill. | St. Luke's Hospital, Kansas City, Mo. |
| Harris, Jack K. | Jacksonville, Fla. | Roper Hospital, Kansas City, Mo. |
| Ireland, Roger G. | Denver | Metropolitan Hospital, Welfare Island, N. Y. |
| Marsten, Edgar L. | Silver Spring, Md. | Gallinger Municipal Hospital, Washington, D. C. |
| Nelson, William C. | Amery, Wis. | Minneapolis General Hospital, Minneapolis |
| Pearson, Linwood J. | Hellertown, Pa. | Germantown Hospital, Philadelphia |
| Rowe, Daniel S. | Shamokin, Pa. | Jefferson Hospital, Philadelphia |
| Schoetzau, Warren W. | North Bergen, N. J. | Metropolitan Hospital, Welfare Island, N. Y. |
| Schubert, Justin C. | North Manchester, Ind. | Santa Monica Hospital, Santa Monica, Calif. |
| Smith, Chandler S. | Robersonville, N. C. | Boston City Hospital, Boston |
| Smith, Grafton A. | Tulsa, Okla. | University of Minnesota Hospitals, Minneapolis |
| Specht, Harry O. J. | St. Louis | Indiana University Medical Center, Indianapolis |
| Whitehorn, Clark A. | Detroit | Detroit Receiving Hospital |

## SURVEY OF LEPERS IN PACIFIC ISLANDS

The Navy Medical Department is making a survey of the one hundred and twenty island communities in the Caroline, Marshall, Palau and Mariana chains of islands in the Pacific Ocean to find how many natives have leprosy and other infectious diseases. For this purpose, the U. S. S. *Whidbey* has been fitted out with examining and operating rooms, a laboratory and roentgenologic and dental departments. In the first two months of the survey, according to Walter Sullivan in the *New York Times*, 65 lepers have been brought to the center on Tinian Island, a vine-buried wilderness where during the war six great air strips were aimed at Tokyo, and where from two pits were loaded the atomic bombs that were dropped on Hiroshima and Nagasaki. Finding lepers in this 2,000,000 miles of ocean area is a big job. The leper colony, which has been in operation only about a month, is temporarily housed in a village built by Americans for the fishermen of Okinawa. The Naval medical officer who volunteered for service with these lepers is Lieutenant (jg) Jack W. Millar of Palo Alto, Calif.

## DR. HOWARD T. KARSNER APPOINTED MEDICAL RESEARCH ADVISER

Dr. Howard T. Karsner, professor of pathology at Western Reserve University, Cleveland, has been appointed medical research adviser to the Surgeon General of the Navy and to the director of the research division of the Navy Bureau of Medicine and Surgery. He is the fifth Navy Department employee to be appointed to a Civil Service position with a salary of more than $10,000 a year under the provisions of Public Law 758 of the 80th Congress, approved June 24, 1948. The law authorized the Navy to fill thirteen positions in the professional and scientific services with a $10,000 to $15,000 salary range.

Dr. Karsner holds a degree of M.D. from the University of Pennsylvania and has studied pathology in Berlin and Vienna. During World War I he served as a captain in the medical reserve corps of the U. S. Army. He is the author of a work on "Human Pathology." As staff consultant, he will assist and advise the Surgeon General concerning evaluation, coordination and development of the Navy Medical Department's research program.

## POSTGRADUATE INSTRUCTION

The following medical officers have been nominated for postgraduate instruction at the institutions indicated: Comdr. James A. Grindell, Washington, D. C., to Armed Forces Staff College, Naval Base, Norfolk, Va.; Lieut. Comdr. John T. M. Giannini, Shepherdsville, Ky., to a fellowship in plastic surgery at various Memphis hospitals on the plastic surgery service of Dr. William M. Adams of Memphis; Lieutenants (jg) Robert E. Fultz, Richmond, Va., to a residency in obstetrics and gynecology at the Naval Hospital, San Diego, Calif., and James H. Harris, Rochelle, Ill., to a residency in obstetrics and gynecology at the Naval Hospital, San Diego, Calif.

## PERSONALS

Lieut. (jg) Thomas J. Coleman of Providence, R. I., has transferred from an active reserve status to the Regular Navy Medical Corps.

Lieut. Comdr. Edward R. Hubbard of Taunton, Mass., and Lieut. (jg) Donald O. Ward of Jamaica Plain, Mass., have been nominated respectively for active duty in the Naval Reserve at the Naval Hospital, Portsmouth, Va., and to a residency in pediatrics in Children's Hospital, Boston.

# AIR FORCE

## OVERSEAS POSITIONS FOR PHYSICIANS

The Air Force is offering overseas opportunities to registered physicians in a civilian capacity. Especially desirable are applicants who have completed a tour of at least two years' active duty with the military service. They will serve both military and civilian personnel. The base pay for these positions is $6,235.20 per annum with a cost of living allowance for each theater. Applicants are required to remain overseas in most theaters for two years. Travel to and from the theater is arranged and provided by the Air Force. Application should be made direct to the Field Extension Office, Overseas Affairs Division, Directorate of Civilian Personnel, Wright-Patterson Air Force Base, Dayton 1, Ohio. Information regarding employment and living conditions will be furnished on request.

## PSYCHOLOGIC TESTS FOR AIRMEN

A group of civilian specialists in psychiatry and psychology, and surgeons of the larger air commands convened at the Air Surgeon's office in the Pentagon, Washington, D. C., December 18-20 to select those psychologic tests which will aid in the selection of pilots. The civilian consultants in the group were: Drs. Russel V. Lee, Palo Alto Clinic, Palo Alto, Calif.; W. Paul Holbrook, Tucson, Ariz.; Laurence F. Shaffer, Columbia University, New York; Walter C. Shipley, Wheaton College, Norton, Mass.; Robert G. Bernreuter, Pennsylvania State College, State College, Pa.; Molly Harrower, New York; Donald W. Hastings, University of Minnesota, Minneapolis; John M. Murray, New York, and Frank Freemont-Smith, New York.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## CALIFORNIA

**Society News.**—Dr. Carroll J. Bellis, Long Beach, addressed the Southeast Branch of the Los Angeles County Medical Association on the "Management of Acute Bowel Obstructions" on January 4.——The Los Angeles Society of Allergy elected Dr. Hyman Miller, Los Angeles, president, and Dr. M. Coleman Harris, Beverly Hills, secretary-treasurer to take office at its January meeting.

**Spastic Disease Center.**—A $1,000,000 center for the relief of infantile paralysis, multiple sclerosis, arthritis and other neuromuscular diseases was opened in November in the former Santa Monica Ambassador Hotel. It is one of four units of the Kabat-Kaiser Institute for the rehabilitation of sufferers from spastic diseases. Other units are situated in Washington, D. C., Oakland and Vallejo. The center's equipment includes swimming pools and a gymnasium.

**Personals.**—Dr. Kenneth W. Haworth, formerly health officer of the Humboldt County Health Department, has become the first full time health officer of Napa County.——Dr. Lowell S. Goin, chief radiologist, Queen of Angels Hospital, Los Angeles, has been appointed a member of the National Advisory Cancer Council for three years to assist in formulating plans and policies of the National Cancer Institute at Bethesda, Md., and to review applications for aid in cancer control and research. Dr. Goin is a past president of the California Medical Association, the American College of Radiology and the Radiological Society of North America.

## CONNECTICUT

**In Memory of Dr. Cushing.**—A portrait bust of Dr. Harvey Cushing, the gift of Miss Malvina Hoffman, sculptor, was unveiled in the Historical Library of Yale University School of Medicine, New Haven, January 15. The casting of the bronze was made possible by the Associates of the Yale Medical Library.

**Hospital Trustees Conference.**—Representatives of 38 Connecticut institutions will meet at the Yale University School of Medicine, New Haven, January 25 at the first Connecticut Hospital Trustees Conference sponsored by the Connecticut Hospital Association and Yale University. The general theme for the conference will be local and regional planning for hospitals. Increased hospital costs, hospitalization plans for welfare cases and hospital programs for postgraduate medical education will be under discussion. Graham L. Davis, Battle Creek, Mich., past president of the American Hospital Association, will speak at the luncheon on postgraduate medical education. Among other speakers will be Ira V. Hiscock, Sc.D., New Haven; C. Rufus Rorem, LL.D., Philadelphia; William H. Horton, Windsor; William H. Putnam, Hartford; Gilbert L. King, Bridgeport, and Drs. Albert W. Snoke and William R. Willard of New Haven.

## DISTRICT OF COLUMBIA

**Medical Chapter of Reserve Officers Association.**—The Reserve Officers Association has established a medical chapter in the District of Columbia Department. Brigadier General Edward A. Evans, national executive director of the association, and Lieutenant Colonel Thomas H. King, president of the District of Columbia Department, officiated at the opening of the chapter at a luncheon at the Army-Navy Club. The charter members of the chapter are: Don. S. Knowlton, Commodore, U. S. N. R.; S. Ross Taggart, Colonel, Surgeon, D. C. National Guard; James B. Mason, Colonel, M. C. Reserve; Raymond Holden, Captain, U. S. N. R.; Luther Gray, Lieutenant Colonel, M. C. Reserve; F. Daniel Suttenfield, Lieutenant Colonel, M. C. Reserve; C. Lee Miller, Major, M. C. Reserve; Francis Threadgill, Major, M. C. Reserve; William Billingsley, Jr., Lieutenant, U. S. N. R., and Matthew Stroup, Captain, M. C. Reserve. The interim officers are Lieutenant Colonel Suttenfield, president, and Lieutenant William K. Billingsley Jr., secretary-treasurer. At a meeting December 9 it was decided that all reserve officers in the medical branches of all services will be eligible for membership.

## ILLINOIS

**Joint Meeting of Doctors and Lawyers.**—The Knox County Medical Society and the Knox County Bar Association held their first joint meeting in forty years December 16 in Galesburg. Mr. J. William Holloway Jr., director of the Bureau of Legal Medicine and Legislation, the American Medical Association, Chicago, spoke on "Legal Medicine and the Professions." A lengthy discussion period followed.

**Personals.**—Dr. Myron J. Tremaine, Evanston, has been presented the degree of Commander with Swords in the Order of Orange-Nassau by the Netherlands Government. Dr. Tremaine, who was in charge of medical activities of the 15th Army during the late war, was accorded the honor "in recognition of excellent service on behalf of the Netherlands government and great collaboration with the Netherlands military forces both during and after the liberation."

### Chicago

**Rheumatic Fever Research Institute.**—The Chicago Heart Association has made a grant of $25,000 to the Rheumatic Fever Research Institute of Northwestern University Medical School from its fund established as a memorial to Morris E. Fishbein Jr., who died as a result of rheumatic fever. Two new laboratories of the institute were recently completed with the aid of another grant of $25,000 from the James Foundation of New York.

**Decrease in Deaths from Tuberculosis.**—According to the Tuberculosis Institute of Chicago and Cook County, the 1948 toll of tuberculosis deaths in Chicago will be about 9 per cent fewer than in 1947. During the first ten months of this year deaths totaled 1,081 as compared with 1,186 for the same period in 1947. However, the number of reported cases shows an increase: In the same period cases reported increased from 3,763 in 1947 to 3,921. During 1948 the institute cooperated with the Municipal Tuberculosis Sanatorium and gave more than 250,000 free chest roentgen examinations in Chicago and 50,000 in the county outside the city.

**Report on Poliomyelitis in Chicago.**—According to the Chicago Health Department, a report on poliomyelitis during the last ten years indicates that nearly 98 per cent of poliomyelitis in Chicago is a mild, widespread disease of young children that leaves no residual paralysis. The report shows that the disease strikes most strongly children aged 1½ to 3 years. Multiple cases of the disease in a family are the rule rather than the exception when there are children from 1½ to 8½ years old in the home. Chicago's data for the period show no significant correlation between climate and the incidence of poliomyelitis.

**Northwestern Honors Dr. Schmidt.**—Dr. Louis E. Schmidt, a member of the Northwestern University Medical School faculty for more than fifty years, was tendered a reception by the university on his eightieth birthday January 8. More than five hundred friends and associates attended. Dr. Schmidt was graduated from Northwestern University Medical School in 1895, and became one of the first doctors in the nation to practice urology as a medical specialty. From 1931 to 1942 he was active in Chicago's campaign for the eradication of syphilis. The present Lewis E. Schmidt Clinic at Northwestern is a consolidation of two previous clinics with which he was associated. Dr. Schmidt became emeritus professor of urology and retired as chairman of the department in May 1947.

## INDIANA

**Personal.**—Dr. Marvin H. Sandorf, a practicing physician of Indianapolis, was among those passing the Indiana Bar Examination in October 1948. Dr. Sandorf is a graduate of Loyola Medical School and a former resident physician at Cook County Hospital, Chicago. He received his LL.B. degree from Tennessee Law School.

**Dr. Ramsey to Edit State Journal.**—Dr. Frank B. Ramsey, Indianapolis surgeon, became editor of the *Journal of the Indiana State Medical Association*, succeeding Dr. E. M. Shanklin of Hammond, who became editor emeritus after sixteen years of service as editor. Dr. Alexander W. Cavins of Terre Haute was named associate editor, the position held previously by Dr. Ramsey.

**Public Relations Field Secretary.**—Larry Richardson, former newscaster over Radio Station WIBC, Indianapolis, has been appointed field secretary of the Indiana State Medical Association. He is a graduate of Indiana University and has been a teacher of radio at Butler University at Indianapolis. Mr. Richardson will assist in developing a public relations program for the association, will speak before lay groups and assist the committee on postgraduate education.

## KANSAS

**Public Health Appointments.**—The Kansas State Board of Health has appointed Dr. Harold G. Nelson, a graduate of the University of Kansas School of Medicine, director of the Division of Epidemiology. He has served as instructor in the department of bacteriology and immunology at the University of Kansas, and from 1946 to 1948 was in charge of the clinical laboratory and associated with the Naval Medical Research Unit Number 4 (Rheumatic Fever) in Dublin, Ga. Dr. Clarence H. Kinnaman, former director, Topeka, will continue in a consultant capacity as epidemiologist and will be directly in charge of special programs. Dr. Andre Baude, a member of the staff of the State Sanatorium for Tuberculosis at Norton since 1942, is acting director of the Division of Tuberculosis Control. He is a graduate of the University of Paris, Faculty of Medicine, 1927.

## LOUISIANA

**Graduate Medical Assembly.**—The annual meeting of the New Orleans Graduate Medical Assembly will be held March 7-10 at the Municipal Auditorium. Fourteen divisions of medicine have selected the following guest speakers: Drs. C. Guy Lane, Boston; Albert F. R. Andresen, Brooklyn; George H. Gardner, Chicago; Russell L. Cecil, New York; Edward H. Rynearson, Rochester, Minn.; Charles A. Poindexter, New York; O. Spurgeon English, Philadelphia; Benjamin P. Watson, New York; Everett L. Goar, Houston, Texas; James S. Speed, Memphis, Tenn.; C. Stewart Nash, Rochester, N. Y.; Colonel James E. Ash, Washington, D. C.; A. Ashley Weech, Cincinnati; Frederic E. Templeton, Seattle; Reginald Smithwick, Boston; John de J. Pemberton, Rochester, Minn.; J. A. Campbell Colston, Baltimore, and Frank Lahey, Boston. Following the meeting a postclinical tour to Mexico is planned for March 12-27. Headquarters in México, D. F., will be the Hotel del Prado. A medical program is being arranged by doctors in México for March 14-15. For information write to the New Orleans Graduate Medical Assembly, Room 105, 1430 Tulane Avenue, New Orleans 12.

## MASSACHUSETTS

**Personal.**—At a November convocation assemblage at Davidson College an alumni citation of merit was presented to Brigadier General James S. Simmons, U.S.A. retired, dean of Harvard School of Public Health, for outstanding contributions in the fields of preventive medicine and public health. General Simmons received his Bachelor of Science degree at Davidson in 1911 and was awarded the honorary degree of Doctor of Science in 1937.

**Massachusetts Physicians Committee.**—On November 22 a group of physicians formed a Massachusetts Physicians Committee to promote free enterprise and preserve the system of private practice in medicine in this country. The committee invites the help of physicians of the commonwealth in studying problems of general concern, in enlightening the public and in lending all aid possible to the government and the people in establishing the nation's health on a secure basis.

## MICHIGAN

**Society News.**—The Michigan Pathological Society on December 11 installed Dr. Donald H. Kaump, Detroit, as president and elected Drs. Richard E. Olsen, Pontiac, president-elect, and Walter A. Stryker, Wyndotte, secretary-treasurer.

**Adult Psychiatric Clinic.**—The Adult Psychiatric Clinic at Harper Hospital, Detroit, has been initiated as a therapeutic unit by the combined efforts of the State Department of Mental Health and community leaders. The clinic will not attempt therapy of certain of the more serious psychiatric conditions. From agencies making a referral it is desirable that the clinic have a social and medical history, and a report of physical examination where this is feasible. A conference with the referring agency is also preferred. A minimum age level for patients is eighteen years. The clinic will operate on a fee basis.

**Beaumont Memorial on Mackinac Island.**—The Council of the Michigan State Medical Society at a recent meeting approved a plan to raise funds by popular subscription to establish the Beaumont Medical Shrine on Mackinac Island. About $30,000 is needed to restore the building where Dr. William Beaumont as a young Army post surgeon began direct observations of the process of digestion through a wound into a patient's stomach, which led to the publication of his book, "Experiments and Observations on the Gastric Juice and the Physiology of Digestion." The restoration of this landmark has been recommended by the Michigan State Medical Society Beaumont Memorial Committee and the Michigan Mackinac Island Commission.

## NEW JERSEY

**Recommendations of Commission on Alcoholism.**—The New Jersey Commission on Alcoholism and Promotion of Temperance, having completed a three year study, has issued a report to the state legislature making recommendations for legislation authorizing the establishment of facilities under the department of health for the treatment of alcoholic addicts and for the prevention of alcoholism. The four point program recommended is designed to guide the New Jersey State Department of Health in developing a positive approach to the problem: (1) provision and operation of facilities necessary for the treatment and rehabilitation of alcoholic addicts; (2) provision of informational and educational services to the public relative to the prevention and treatment of alcoholism; (3) initiation and sponsorship of research programs to increase scientific knowledge in the field, and (4) coordination of its efforts with other agencies whose services can contribute to the objectives of the department.

## NEW YORK

**Postgraduate Lecture.**—The Medical Society of the State of New York, with the cooperation of the New York State Department of Health, has arranged a postgraduate lecture for the Onondaga County Medical Society at the University Club, Syracuse, February 1, 8:30 p. m., when Dr. Marcy L. Sussman, New York, will speak on "Recent Radiologic Contributions to the Study of Heart Disease."

**Rochester Committee on Arthritis and Rheumatism.**—A Rochester Committee to represent the Arthritis and Rheumatism Foundation organized a few months ago has been formed. Rochester is one of thirty-eight centers the foundation has designated to represent it locally and to assist in its fund-raising effort. Headquarters has been established at 1441 East Avenue, in care of the Medical Society of the County of Monroe. The Governing Committee is headed by Dr. Jacob D. Goldstein, Rochester.

**Cancer Teaching Day.**—A Cancer-Teaching Day will be held at the Hermann M. Biggs Memorial Hospital, Ithaca, January 19 beginning at 4 p. m., under the auspices of the Medical Society of the County of Tompkins and the Tompkins County Department of Health, the Medical Society of the State of New York and the New York State Department of Health. The program is as follows: Dr. Norman Treves, New York, "Cancer of the Breast"; Dr. John S. LaDue, New York, "Operative Risk and Pre- and Post-Operative Care of Patients with Cancer"; Dr. Clyde L. Randall, Buffalo, "Significance and Management of Abnormal Vaginal Bleeding," and Dr. Albert F. R. Andresen, New York, "Gastrointestinal Cancer." A buffet supper will follow at 6:30 p. m., for which the required advance reservations may be obtained from N. Stanley Lincoln, M.D., Hermann M. Biggs Memorial Hospital, Ithaca, N. Y.

### New York City

**John Osborn Polak Memorial.**—Cornerstone-laying ceremonies were held December 17 for the John Osborn Polak Memorial, an addition to the Long Island College Hospital. It contains a suite of six operating rooms and other facilities. Dr. Polak was professor of obstetrics and gynecology at the Long Island College of Medicine and at the hospital. He died June 29, 1931.

**Annual President's Dinner.**—The Medical Society of the County of Kings and the Academy of Medicine of Brooklyn will hold its fifth annual president's dinner January 26 at Hotel St. George, Brooklyn, Harry D. Gideonse, LL.D., president of Brooklyn College, will speak on "Free Science and the Future of an Open Society." Presentation of the President's Medal and Scroll will be made to Dr. A. W. Martin Marino.

**Director of Neurological Surgery Appointed.**—Dr. J. Lawrence Pool has been named director of Neurological Surgery Service at the Neurological Institute of the Presbyterian Hospital and professor of neurological surgery and executive officer of the department, effective January 1. He has been associated with the Columbia-Presbyterian Medical Center since 1934. Dr. Pool was graduated from the Columbia University College of Physicians and Surgeons in 1932. He was chief of neurosurgery for four months in World War II at the Army's Thomas M. England Hospital in Atlantic City.

**Award the Benson Fellowship.**—A fellowship for medical research commemorating the late Philip A. Benson has been awarded to Dr. Irving Rappaport, an instructor at the Long Island College of Medicine. Dr. Rappaport has had training and experience as a malariologist and parasitologist in tropical medicine in Australia, New Guinea, the Philippines and the U. S. Army Medical School. The Philip A.

Benson Memorial Fund was formed by contributions from Mr. Benson's friends and by savings banks of New York State, the association of which Mr. Benson was president. Mr. Benson was a trustee of the college for twelve years. It is anticipated that the fund will eventually be increased to provide for a full time professorship at the college.

**Coordinate Physical Medicine Program.**—Columbia University on January 1 embarked on a new program of coordination and integration of the physical medicine program which has been developed under impetus from a grant of $400,000 from the Baruch Committee on Physical Medicine. Dr. Robert C. Darling, associate professor of medicine, director of research in physical medicine and chairman of the Physical Fitness Sub-Committee of the Baruch Committee, will be coordinator of physical medicine and rehabilitation. The new program will deal with the instructional and research activities in physical medicine at Columbia-Presbyterian Medical Center; the Institute for the Crippled and Disabled, which is affiliated with Columbia; the instructional program in physical and occupational therapy at the Medical Center and Teachers College, and training projects for both technical and medical personnel at the Medical Center and eight other hospitals in New York City. Dr. Darling is a graduate of the Harvard Medical School, Boston, 1934.

## OHIO

**Seminar for General Practitioners.**—The Society of General Physicians, Cincinnati, is offering a seminar on "Pathologic Physiology of Disease," for general practitioners, in collaboration with the University of Cincinnati College of Medicine. The meetings will be held in Room 110 of the college on Tuesdays and Thursdays beginning January 18 and extending through February 10. Sixteen lecturers under the direction of Dr. Marion A. Blankenhorn, Cincinnati, will participate in the seminar.

**Attack on Unethical Practices.**—The Cleveland Academy of Medicine and the Cleveland Better Business Bureau are making a joint attack on unethical and fraudulent practices on the part of physicians, other classes of practitioners and firms which supply them with materials and appliances. The joint effort is the result of a study made by the Academy of Medicine and subsequent conferences with officials of the Better Business Bureau. Action was taken by the academy to the end of fostering public confidence in the medical profession. Six conditions are to be checked:

(1) fraudulent medical advertising; (2) rebating to physicians from the sale of eyeglasses; (3) rebating from the sale of diagnostic and therapeutic mechanical apparatus; (4) the control of unlicensed and limited licensed practitioners who overstep the bounds of legal limitations; (5) the practice by certain druggists of giving physicians rebates from remedies sold to patients, and (6) the activities of some physicians who falsely promise impossible cures and fraudulently treat incurable diseases.

It was felt that the first three items listed should receive the initial concentrated effort. The academy has granted the bureau $2,500 with which to start the campaign.

## OREGON

**Memorial to Dr. Mount.**—A gift of $5,000 to the library of the University of Oregon Medical School, Portland, has been made in memory of Dr. Frank R. Mount, former assistant clinical professor of medicine at the university, by Mrs. John E. Weeks. This makes a total of $6,825 given to the library in his memory by various persons. Dr. Mount died Oct. 11, 1947.

**Research Laboratories Completed.**—Completion of research laboratories at the University of Oregon Medical School, Portland, will make possible immediate acceleration of the virus research program, according to Dr. Arthur Frisch, director. The animal quarters, costing $125,000 and paid for with state funds, consist of thirty rooms. Financing of the virus section improvements was made possible through the gift of the National Foundation for Infantile Paralysis Chapters in Josephine and Multnomah counties.

## SOUTH DAKOTA

**Meeting of Council and District Officers.**—The first annual meeting of the Council and District Officers of the South Dakota State Medical Association was held at the Marvin Hughitt Hotel, Huron, January 9. Subjects discussed included "Duties of the District Officers" and "Relation of the District to the State Association," "Conduct of the District Society," "Public Relations" and "Prepayment of Medical Care."

## WEST VIRGINIA

**Organize General Practice Group.**—A West Virginia Chapter of the American Academy of General Practice has been organized at Charleston. The seventeen charter members present elected the following officers for 1949: President, Dr. Tyler R. Boling, Grantsville; vice president, Dr. Ralph Frazier, Fayetteville; secretary, Dr. Carl B. Hall, Charleston.

**Personals.**—Dr. Joseph U. Rohr of Charleston has been named by Governor Clarence W. Meadows as superintendent of the Andrew S. Rowan Memorial Home at Sweet Springs, effective November 1. He succeeds Dr. Henry H. Hancock, superintendent since 1946, who resigned to resume private practice. Dr. Luke W. Frame of Morgantown has been named director of the division of communicable disease of the state health department, succeeding Dr. Robert E. Gibson, Charleston, resigned.

**Society News.**—At a recent meeting of the Central Medical Society in Buckhannon, Dr. William W. Huffman of Gassaway, was elected president and Dr. Theresa O. Snaith of Weston, secretary-treasurer. The meeting was attended by over fifty doctors, members of the auxiliary and guests.——The West Virginia Academy of Ophthalmology and Otolaryngology at the annual fall meeting elected Dr. Sobisca S. Hall, of Clarksburg, president; Dr. Melvin W. McGehee, Huntington, secretary, and Dr. Frederick C. Reel, Charleston, treasurer.

## PUERTO RICO

**Puerto Rico Medical Association.**—At the annual meeting of the Puerto Rico Medical Association Dec. 7, 1948 in San Juan Dr. Manuel A. Astor was reelected chairman; Dr. Jenaro Barreras, vice-chairman; Dr. J. Bassora Defillo, secretary; Dr. Jaime F. Pou-Valldejuli, treasurer, and Dr. Carlos Munoz McCormick, delegate to the American Medical Association. Dr. Manuel G. Rodriguez was reelected chairman of the chamber of delegates.

## GENERAL

**Cerebral Palsy Meeting.**—The American Academy for Cerebral Palsy will hold its Second Annual Meeting at the Palmer House in Chicago January 27-28. A scientific meeting will be held on Friday afternoon and Saturday morning.

**National Society for Medical Research.**—The annual board of directors meeting of the National Society for Medical Research will be held at 2 p. m. February 6 in the Palmer House, Chicago, in connection with the annual Conference on Medical Education and Licensure.

**Urologists Meeting.**—The Western Section of the American Urological Association will meet January 17-19 at the Hotel del Coronado, Coronado, Calif. The Robert V. Day Lecture on "Present Status of Prostatic Carcinoma" will be delivered by Dr. Charles B. Huggins, Chicago. Homer W. Smith, New York, has been invited to speak on "Modern Theory of Urine Formation." The Joseph F. McCarthy Award paper will be given Wednesday morning by Dr. John W. Dorsey, Long Beach, Calif., on "Solitary Hydrocalyx."

**Teachers of Clinical Radiology to Meet.**—The sixteenth annual Conference of Teachers of Clinical Radiology will be held at the Drake Hotel, Chicago, February 5 under the sponsorship of the American College of Radiology. There will be round table discussions at which teachers of clinical radiology can discuss problems of mutual interest. The first Conference on Radiology in Rural Health will be held from 2:30 to 6 p.m. February 5 after the teachers' conference. The meeting will take up possible methods of bringing specialized radiologic services to rural areas.

**Increased Number of Student Nurses.**—More than 43,000 students entered schools of nursing in the United States during 1948, according to the American Hospital Association. The figure represents an increase of nearly 5,000 students over the 1947 total, 12,000 more than in 1946 and the largest number of student nurses ever recruited during a peacetime year. Enrolment in schools in 38 states increased from 1 to 73 per cent; in 8 states decreased admission was reported. The increase is believed to be the result of two national recruitment drives during the last two years sponsored by the American Hospital Association, American Medical Association, American College of Surgeons, American Red Cross, U. S. Public Health Service, the National Committee on Careers in Nursing and the Advertising Council.

**Six Scientists Receive Awards.**—Six scientists were presented Amory Awards totaling $21,000 for research in disorders of the human reproductive organs at a meeting of the American Academy of Arts and Sciences in Boston December 8. The awards were given to Dr. W. J. Kolff of Holland for developing the artificial kidney; Dr. George N. Papanicolaou, New York, for the early diagnosis of cancer by the detection of malignant cells in secretions; Professor Guy F. Marrian, Edinburgh, Scotland, for research on the chemistry of sex hormones; Selman A. Waksman, Ph.D., New Brunswick, N. J., for his discovery of streptomycin, and Dr. Alexander B. Gutman, New York, and Dr. Charles B. Huggins, Chicago, for their work in the diagnosis and treatment of cancer of the prostate. The prizes were established by Francis Amory's bequest to the American Academy of Arts and Sciences in 1912 for stimulating invention and research to provide for the treatment and cure of "the diseases of the human sexual generative organs," especially for the relief of "retention of urine, cystitis, prostatitis and those distressing disorders so common to old men." Prizes are awarded every seven years by the academy in accordance with the bequest.

**Funds Allocated for Research on Hypertension.**—The Board of Trustees of the American Foundation for High Blood Pressure have announced the allocation of funds to the following investigators for research in hypertension and arteriosclerosis:

| | |
|---|---|
| Thomas C. Barnes, Sc.D., Hahnemann Medical College Philadelphia | $ 1,000 |
| Stanley E. [illegible] New York | 5,000 |
| Norman E [illegible] San Francisco | 3,500 |
| Meyer Fri [illegible] n Francisco | 5,300 |
| Sydney M [illegible] Faculty of Medicine, Montreal, Canada | 3,000 |
| David M. Greenberg, Ph.D., University of California, Berkeley, Calif. | 8,640 |
| Keith S. Grimson, Duke University Hospital, Durham, N. C. | 5,000 |
| Albert I. Lansing, Ph.D., Washington University School of Medicine, St. Louis | 7,182 |
| Arnold Lazarow and John W. Patterson, Ph.D., Western Reserve University, Cleveland | 5,000 |
| Jessie Marmorston, University of Southern California, Los Angeles | 5,000 |
| Campbell Moses, University of Pittsburgh School of Medicine, Pittsburgh | 1,900 |
| Frederick J. Moore and Norman C. Flau, University of Southern California, Los Angeles | 5,000 |
| Jean Oliver, Long Island College of Medicine, New York | 2,800 |
| Ernest W. Page, University of California, San Francisco | 3,000 |
| Lelland J. Rather, Stanford University School of Medicine, San Francisco | 5,000 |
| George E. Wakerlin, University of Illinois, Chicago | 5,000 |
| A. Earl Walker, Johns Hopkins University, Baltimore | 4,000 |
| Harold Wiggers, Ph.D., Albany Medical College, Albany, N. Y. | 2,700 |
| Eugene B. Ferris, University of Cincinnati, Cincinnati | Amount to be Determined. |

## CANADA

**Society News.**—The Montreal Medico-Chirurgical Society, meeting February 4, will hear Drs. John F. McIntosh, Frederick G. Kalz, Max Ratner, and Emerson C. Smith, all of Montreal, discuss "The Relation of Urinary Urease to Crystalluria and Recurrent Stone Formation, with Report of Cases." Dr. Priscilla White, Boston, will speak on "Diabetes and Pregnancy." At the February 18 meeting a symposium on "Cervicobrachial Pain" will be held with speakers Drs. Francis L. McNaughton, Simeon J. Martin, James G. Shannon and Herbert F. Moseley, all of Montreal.

## LATIN AMERICA

**Inter-American Congress of Radiology.**—The Third Inter-American Congress of Radiology will be held in Santiago de Chile November 11-17 under the sponsorship of the Chilean government. Official subjects of the congress will be radiological exploration of the cardiovascular system with opaque material; diagnosis and simple radiologic exploration of the skull, and radiation treatment of cancer of the tongue and of the cervix. Because of the great demand for South American transportation during the winter months, those in the United States who wish to attend should write Dr. James T. Case, 55 East Washington Street, Chicago 2, coordinator between the executive committee of the congress and radiologists of the United States.

**Inter-American Congress on Brucellosis.**—The Second Inter-American Congress on Brucellosis, under the auspices of the Pan-American Sanitary Bureau, was held at Mendoza and Buenos Aires, Argentina, November 17-26. The United States was represented officially by Dr. James H. Steele, Chief, Veterinary Public Health Division, U. S. Public Health Service, Atlanta, Ga., who was named chairman of the delegation, and Dr. C. K. Mingle of the Bureau of Animal Industry. Other American participants invited by the Congress were Dr. Harold Harris, New York; Horace M. Powell, Sc. D., Indianapolis; Drs. Leo Lowbeer, Tulsa, Okla., and Joseph F. Griggs, Claremont, Calif.

The meeting at Mendoza was devoted to research and epidemiology papers by representatives of Argentina, Chile, Colombia, Peru, Venezuela, Mexico and the United States. Dr. Steele presented a paper on "The Epidemiology of Brucellosis in the United States." Dr. Mingle responded at the opening session for the visiting delegates to the speech of welcome by the Minister of Health, Dr. Luis Carrillo. Dr. Carlos Crivellari, director of public health, Argentine Republic, was chosen president of the congress. Dr. Miguel Bustamente, secretary, Pan-American Sanitary Bureau, assisted Dr. M. Ruiz Castaneda, secretary.

The Mendoza area, in the foothills of the Andes, has an extensive goat industry, and most of the brucellosis reported is of the melitensis type. The delegates visited the surrounding country to see the goat industry and observe the conditions under which the shepherds became infected. The close proximity to human habitation of the corrals and the necessary handling of the animals in milking cause human exposure to animal infection. In the urban areas many human cases are traced to unpasteurized cheese of goat origin. There are few cattle or swine in this region, and no Brucella abortus or Brucella suis cases among human beings are reported.

The delegates had an opportunity to see the pampas after the Mendoza session closed when they were en route to Buenos Aires. The Province of Buenos Aires, which surrounds the city, has a dense animal population of cattle, swine, horses and sheep, although the major portion of the sheep industry is further south in Patagonia.

The meetings were resumed in Buenos Aires on November 22 and closed on November 26. The Buenos Aires meeting was mainly concerned with the discussion of the diagnosis and therapy of human brucellosis. Dr. Harris spoke on "Diagnosis and Treatment of Brucellosis," Dr. Griggs on "Bacterial Allergy," Dr. Powell on "Therapy" and Dr. Lowbeer on "The Pathology of Swine Brucellosis." Dr. M. Ruiz Castaneda of Mexico presented an excellent paper on "The Treatment of Brucellosis with Aureomycin." The congress created two permanent committees to study the standardization of human serologic diagnostic methods and animal disease eradication. The success of both groups will depend on having a standard antigen with which to compare other antigens. The congress concluded that the antigen of the Bureau of Animal Industry, U. S. Department of Agriculture, would be the best to use, as it is available in large quantities and could be readily distributed. Similar studies will also be carried on for animal serology. The congress further agreed that brucellosis cannot be controlled in man until it is controlled in animals.

The congress voted to accept the invitation of the United States to hold the third Inter-American Congress on Brucellosis in Washington, D. C., in October 1950. Dr. W. William Spink, Minneapolis, has been named chairman of the third congress and Dr. M. Ruiz Castaneda is to continue as secretary.

# Marriages

J. Woodhull Overton, New York, to Mrs. Joan Blair Havemeyer of Las Vegas, Nev., in Boulder City, Nev., October 25.

Robert J. Duncan, La Salle, Ill., to Miss Jane Ruth Weymouth of Avalon, Wis., in Delavan, Wis., Nov. 6, 1948.

Robert L. Alexander, Cleveland, to Miss Sansa Rita O'Connor in Shaker Heights, Ohio, October 23.

George Ralph Hatcher, Valhalla, N. Y., to Miss Mary Louise Heinze of Fostoria, Ohio, October 24.

Jack Hanson Powell Jr., to Miss Margaret Valentine Peniston, both of Newman, Ga., in October.

James Blair Martin to Miss Jane Pierson, both of Charleston, S. C., in Macon, November 6.

Adelbert Ames III, Hanover, N. H., to Miss Judith Quentin Derby in Oyster Bay, L. I., October 16.

Condon Thomas Hagan, Wichita, Kan., to Miss Mary Ann Claffy of Columbia, S. C., November 8.

Patrick James Finucane to Miss Jeane Marie Kinsman, both of Eau Claire, Wis., November 6.

Joseph F. Zigarelli, Paterson, N. J., to Miss Eileen Joan Reilly of Englewood, November 6.

John R. Markette to Miss Dollie Mae Swalm, both of Brookhaven, Miss., October 16.

Theodore B. Van Itallie, New York, to Miss Barbara Cox of Bangor, Me., September 25.

Henry C. Scholer to Miss Dorothy Mae Eyler, both of Monmouth, Ill., October 16.

Melvin Raymond Salk to Miss Zelda Weiner, both of Chicago, November 28.

# Deaths

**Charles Malden Oman** ⊕ Medical Director, Rear Admiral, U. S. Navy, retired, Beacon, N. Y.; born in Columbia County, Pa., Oct. 23, 1878; University of Pennsylvania Department of Medicine, Philadelphia, 1901; commissioned assistant surgeon in the U. S. Navy on Feb. 2, 1902; served in the Philippine, Cuban and Mexican campaigns; during World War I commanded the hospital ship Comfort and later the Navy Base Hospital at Brest, France; commanded the Naval Dispensary, Washington, D. C., from 1928 until 1931; served as medical officer of the third Naval District; in 1941 became the first medical officer in command of the Navy Medical Center, Bethesda, Md.; in 1942 was transferred to the retired list but continued to serve as commandant of the Naval Convalescent Hospital at Harriman, N. Y., until Nov. 6, 1945; member of the board of governors of the American College of Surgeons, member of the New York Society of Tropical Medicine, and for many years a member of the National Board of Medical Examiners; awarded the Navy Cross for distinguished service as officer in command of the hospital at Brest, and the Italian Red Cross medal for work in the Massina earthquake in 1909; author of "Minor Surgery" and "Doctors Aweigh"; died November 1, aged 70, of coronary occlusion.

**George Corwin Beach Jr.,** ⊕ Major General, M. C., U. S. Army, and Assistant Surgeon General of the Army in command of the Army Medical Center, Washington, D. C.; born in Topeka, Kan., Oct. 28, 1888; University Medical College of Kansas City, Mo., 1911; in 1917 commissioned a first lieutenant in the regular army, and in the same year graduated from the Army Medical School; assigned to the Panama Canal Zone as post surgeon; later chief of medical services at the Sternberg General Hospital in Manila; formerly served at the Letterman General Hospital in San Francisco and the Mayo Clinic in Rochester, Minn.; at one time commanding officer of the Station Hospital, Fort Sam Houston, Texas; in 1930 awarded the Distinguished Service Medal for exceptionally meritorious service; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the Association of Military Surgeons of the United States; died in the Walter Reed General Hospital, November 18, aged 60.

**John Beekman Potts,** Omaha; born in Morrisonville, Ill., July 14, 1876; University of Nebraska College of Medicine, Omaha, 1907; joined the faculty of his alma mater in 1912 as clinical assistant in otolaryngology and rhinology; became instructor in 1914, assistant professor in 1925, associate professor in 1931 and since 1937 professor of otorhinolaryngology emeritus; specialist certified by the American Board of Otolaryngology; member of the American Medical Association, Association for the Study of Internal Secretions, American Academy of Ophthalmology and Otolaryngology, American Laryngological Association, American Laryngological, Rhinological and Otological Society and the American Otological Society; served overseas during World War I; affiliated with the Bishop Clarkson Memorial Hospital, Nebraska Methodist Episcopal Hospital and University of Nebraska Hospital; consultant for the Veterans Bureau; died October 29, aged 72, of acute pulmonary edema.

**Warren Douglas Horner** ⊕ San Francisco; born in Klamath Falls, Ore., in 1890; University of California Medical School, San Francisco, 1916; associate clinical professor of ophthalmology at his alma mater; vice chairman of the Section on Ophthalmology of the American Medical Association in 1947; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, American Ophthalmological Society, Association for Research in Ophthalmology, Western Ophthalmological Society and Pacific Coast Oto-Ophthalmological Society; served during World Wars I and II; president of the board of directors of the Lux Technical Institute; affiliated with St. Mary's Hospital, Children's Hospital and the U. S. Marine Hospital; died October 22, aged 58, of carcinoma of the prostate.

**John Thomson Crebbin,** New Orleans; born in Lawrence, Kan., Dec. 8, 1872; the Hahnemann Medical College and Hospital, Chicago, 1900; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; at one time on the faculty of the New Orleans Polyclinic; for many years president of the state board of nursing examiners, which he helped to organize; formerly practiced in Shreveport, La., where he was on the staffs of the Pines Sanatorium, North Louisiana Sanitarium and Shreveport City Hospital; served as superintendent of the Eye, Ear, Nose and Throat Hospital; died in Mercy Hospital October 20, aged 75, of cerebral arteriosclerosis, hypertension and lymphoma.

**George F. Adair,** Lynbrook, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1900; died recently, of arteriosclerosis.

**Henry Rihl Alburger** ⊕ Indianapolis; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the American Society of Clinical Pathologists; at one time on the faculty of Indiana University and of the University of Pennsylvania; served on the staffs of the Methodist and St. Vincent's hospitals; formerly on the staff of the City Hospital; affiliated with St. Francis Hospital, where he died October 7, aged 74.

**Romus Arnold,** Carthage, Mo.; the Hahnemann Medical College and Hospital, Chicago, 1888; served during World War I; died October 11, aged 83, of arteriosclerosis.

**Curtis Leroy Baker** ⊕ Kirkpatrick, Ohio; Medical College of Indiana, Indianapolis, 1894; died October 15, aged 78.

**Canada Asbery Beeler,** Cherryvale, Kan.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1903; member of the American Medical Association; died October 1, aged 75, of coronary arteriosclerosis.

**Charles Gideon Bell,** Canton, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1903; member of the American Medical Association; served during World War I; for many years chairman of the board of directors of the Canton Exchange Bank; local surgeon for the Illinois Central Railroad; died in St. Dominic's Hospital, Jackson, October 27, aged 65, of heart disease.

**Joseph Louis Belliotti** ⊕ Providence, R. I.; University of Buffalo School of Medicine, 1916; fellow of the American College of Surgeons; served during World Wars I and II; member of the board of trustees of state colleges; affiliated with the Notre Dame Hospital, Central Falls, Westerly (R. I.) Hospital, State Infirmary, Howard, Roger Williams Hospital, Charles V. Chapin Hospital and St. Joseph's Hospital, where he died October 27, aged 54, of coronary occlusion.

**James Harrington Biram** ⊕ Hartford, Conn.; Cornell University Medical College, New York, 1910; fellow of the American College of Surgeons; a medical officer serving in France during World War I; served on the staff of Hartford Hospital and as medical director of the Colt Manufacturing Company; died in Granby, October 30, aged 67, of heart disease.

**Irving DeLoss Blanchard,** Boston; Yale University School of Medicine, New Haven, 1897; died in West Newton, September 30, aged 74, of arteriosclerotic heart disease.

**Henry Montague Bonner,** Morehead City, N. C.; Medical College of Virginia, Richmond, 1897; on the staff of the Morehead City Hospital; died in Laurinburg October 19, aged 73, of myocarditis.

**Charles D. Boyd,** Kaukauna, Wis.; Rush Medical College, Chicago, 1891; member of the American Medical Association; past president of the Outagamie County Medical Society; served as trustee of the Wisconsin Anti-Tuberculosis Association; formerly health officer and mayor; a founder and, until 1946, superintendent and medical director of the Riverview Sanatorium, a position he held for thirty-two years; on the staff of St. Elizabeth's Hospital in Appleton; died October 1, aged 79, of nephritis.

**George W. Brickbauer,** New Holstein, Wis.; Homeopathic Medical College of Missouri, St. Louis, 1895; formerly president of the State Bank in Plymouth and village president of Elkhart Lake; at one time director and president of the chamber of commerce of Sheboygan; died October 24, aged 81, of cerebral hemorrhage.

**Terrell Bridges,** Montevallo, Ala.; Birmingham Medical College, 1915; member of the American Medical Association; died October 27, aged 61, of coronary thrombosis.

**John T. Burnite,** Harrisburg, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1904; member of the American Medical Association; affiliated with Polyclinic Hospital, where he died October 20, aged 68, of coronary disease.

**Mary Allen Callaway-Joplin,** Boise, Idaho; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1902; member of the American Medical Association; served for two terms as a member of the state house of representatives; died in a local hospital October 15, aged 69, of carcinoma of the ovary.

**Henry Jones Carswell,** Waycross, Ga.; University of Georgia Medical Department, Augusta, 1908; member of the American Medical Association; served overseas during World War I; died October 3, aged 63.

**Horace Fordyce Coburn,** Wilton, N. H.; Harvard Medical School, Boston, 1903; died October 13, aged 76.

**Walter Alton Coole** ⊕ Houston, Texas; Baylor University College of Medicine, Dallas, 1930; served as secretary of the Harris County Medical Society; formerly an officer in the U. S. Navy; served during World War I; died suddenly, October 16, aged 48.

**Henry Knox Craig,** Washington, D. C.; Columbian University Medical Department, Washington, 1895; formerly librarian and curator of the museum at George Washington University School of Medicine; died in the Gallinger Hospital October 22, aged 76.

**Leman Dow Cruice** ⊕ Major, U. S. Army, retired, Alhambra, Calif.; Jefferson Medical College of Philadelphia, 1913; entered the medical corps of the U. S. Army in 1917; retired May 22, 1920 for disability in line of duty; served during World War I; died in Pasadena, recently, aged 60, of coronary occlusion.

**James Floyd Darby,** St. Ignace, Mich.; Michigan College of Medicine and Surgery, Detroit, 1895; past president of the Chippewa-Mackinac Counties Medical Society; died September 25, aged 77.

**Benjamin Shadrach Davis,** Plymouth, Pa.; Jefferson Medical College of Philadelphia, 1917; served as secretary of the board of health of Plymouth, as police and fire surgeon and for two terms as coroner's physician; affiliated with the Wyoming Valley Homeopathic Hospital, Wilkes-Barre, where he died October 10, aged 55, of cerebral hemorrhage.

**Leon Curtis Davis** ⊕ Greenville, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1910; affiliated with King's Daughters' Hospital; died in Sanatorium October 27, aged 62, of pulmonary tuberculosis.

**Nettie Austin Murphy Dorris** ⊕ Paris, Ill.; University of Louisville (Ky.) Medical Department, 1905; formerly health superintendent of district number 13; served as superintendent of the Illinois mobile health unit with headquarters in Springfield; died in the Cottage Hospital in Galesburg, October 10, aged 71, of nephritis.

**Robert Edward Dyer,** Chicago; University of Illinois College of Medicine, Chicago, 1919; member of the American Medical Association; formerly on the faculty of the Loyola University School of Medicine; on the staffs of Mercy, St. Joseph and Ravenswood hospitals; died October 29, aged 54, of coronary thrombosis and hypertension.

**Frank Birch Easton,** Craftsbury Common, Vt.; Harvard Medical School, Boston, 1904; member of the American Medical Association; affiliated with the Orleans County Memorial Hospital, Newport, where he died recently, aged 70, of uremia and chronic nephritis.

**Wiley Sims Embrey,** Texarkana, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1896; served during World War I; died October 2, aged 78, of heart disease.

**Archibald Parker Evans,** Kings Park, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1905; served during World War I; for many years affiliated with Kings Park State Hospital; died October 21, aged 68, of chronic myocarditis.

**George H. Eversole,** Caledonia, Mo.; Missouri Medical College, St. Louis, 1886; died October 4, aged 85.

**Frank B. Farrington,** Kirksville, Mo.; St. Louis University School of Medicine, 1905; died in Dearborn, Mich.; October 24, aged 74.

**J. B. Freeland,** Dyersburg, Tenn. (licensed in Tennessee in 1910); died recently.

**Daniel Sylvester Gardner,** Massillon, Ohio; Western Reserve University Medical Department, Cleveland, 1887; chairman of the Selective Service Board during World War I; on the staff of Massillon City Hospital, where he died October 26, aged 81, of carcinoma of the prostate.

**Earnest Reuel Goodloe** ⊕ Paducah, Ky.; University of Nashville (Tenn.) Medical Department, 1903; past president of the Southwestern Kentucky Medical Association; past president and secretary of the McCracken County Medical Society; formerly postmaster of Little Cypress; on the staff of the Illinois Central and Riverside hospitals; died October 23, aged 69, of carcinoma of the pancreas.

**John Pugh Hall** ⊕ Pittsburgh; College of Physicians and Surgeons, Baltimore, 1892; served during World War I; died October 21, aged 81.

**Julius Hammer,** New York; Columbia University College of Physicians and Surgeons, New York, 1902; member of the American Medical Association; died October 17, aged 74.

**Frank Cleveland Hart,** Seattle; University of Oregon Medical School, Portland, 1915; served during World War I; died in Walla Walla September 29, aged 62, of heart block.

**Edward Leo Herlihy** ⊕ Bangor, Me.; Medical School of Maine, Portland, 1920; fellow of the American College of Surgeons; affiliated with the Eastern Maine General Hospital; died October 31, aged 53.

**Gilbert Austin Hoppes,** Anderson, Ind.; Indiana University School of Medicine, Indianapolis, 1912; died in the Ball Memorial Hospital, Muncie, October 22, aged 58, of hypertensive cardiovascular renal disease.

**William Forrest Howard** ⊕ Pocatello, Idaho; University Medical College of Kansas City, Mo., 1899; an Associate Fellow of the American Medical Association; fellow of the American College of Surgeons; served during World War I; formerly secretary of the Pocatello Medical Society; past president of the Idaho State Medical Association; served as a member of the state board of medical examiners and as city physician; affiliated with the Pocatello General and St. Anthony's hospitals; died October 19, aged 80.

**William Bell White Howe,** Hendersonville, N. C.; Medical College of the State of South Carolina, Charleston, 1906; member of the board of health; honorary member of the staff of Patton Memorial Hospital; died October 4, aged 67, of coronary disease.

**Hans Joergensen** ⊕ Greenport, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1922; died in the Eastern Long Island Hospital, September 20, aged 60, of cerebral hemorrhage.

**Llewelyn L. Jones** ⊕ Glendale, Calif.; University of Nashville (Tenn.) Medical Department, 1899; on the staffs of the Physicians and Surgeons Hospital and Glendale Sanitarium and Hospital, where he died October 15, aged 77, of injuries received when struck by an automobile.

**Thomas Samuel Jones,** Waukee, Iowa; Drake University College of Medicine, Des Moines, 1913; served as mayor and president of the school board; died in Iowa Methodist Hospital, Des Moines, October 26, aged 73, of pulmonary embolism.

**George Lygurgus Karras,** Gary, Ind.; Dalhousie University Faculty of Medicine, Winnipeg, Manitoba, Canada, 1926; died September 30, aged 50.

**Edmond G. Klamke** ⊕ Alexandria, La.; Københavns Universitet Laegevidenskabelige Fakultet, Denmark, 1901; member of the American Public Health Association; director of the Rapides Parish health unit; served during World War I; killed in an automobile accident near Morrow October 13, aged 73.

**Joseph Matthew Klein,** North Brunswick, N. J.; University of Vermont College of Medicine, Burlington, 1909; died October 20, aged 70, of coronary thrombosis.

**James Andrew La Gasa** ⊕ Tacoma, Wash.; Jefferson Medical College of Philadelphia, 1908; fellow of the American College of Surgeons; member of the Washington State Medical Association; at one time on the staffs of Tacoma General and St. Joseph's hospitals; died in Tucson, Ariz., October 7, aged 65, of coronary occlusion.

**Otto Laist** ⊕ San Francisco; College of Physicians and Surgeons of San Francisco, 1900; an Affiliate Fellow of the American Medical Association; on the staff of St. Joseph's Hospital; died October 13, aged 77, of congestive heart failure.

**William Carle Landis,** Claypool, Ind.; Bennett Medical College, Chicago, 1907; served during World War I; died in the Elkhart (Ind.) General Hospital October 19, aged 67, of vesicointestinal fistula.

**Claude B. Leggett,** Abilene, Texas; Southwestern University Medical College, Dallas, 1905; member of the American Medical Association; affiliated with St. Ann Hospital and Hendrick Memorial Hospital; died October 25, aged 68, of cerebral hemorrhage.

**William Levy** ⊕ Suffield, Conn.; Yale University School of Medicine, New Haven, 1911; for many years local medical examiner and health officer; on the staff of Springfield Hospital; died September 15, aged 58, of carcinoma.

**Llewellyn Roy Lewis,** Los Angeles; Northwestern University Medical School, Chicago, 1916; member of the American Medical Association; served as a member of the consulting editorial staff of the supplement of the *International Abstract of Surgery (Surgery, Gynecology and Obstetrics)*; died October 24, aged 58.

**Robert Stephen Lilla** ⊕ Captain, U. S. Army, retired, Nucla, Colo.; Jefferson Medical College of Philadelphia, 1925; entered the U. S. Army on July 1, 1926; retired for disability in line of duty Sept. 30, 1933; died November 1, aged 49, of tuberculosis.

**Hugh Harrison Linn,** Bowringpet, Deccan, India; Northwestern University Medical School, Chicago, 1909; for many years a medical missionary; died recently, aged 70.

**Rossitter J. Lloyd** ⊕ Olyphant, Pa.; Baltimore Medical College, 1897; member of the Radiological Society of North America, Inc.; died October 28, aged 70.

**Joseph Allan Locke,** Tacoma, Wash.; McGill University Faculty of Medicine, Montreal, Canada, 1910; served with the Canadian Army during World War I; *died recently, aged 62.*

**Frank Peter McCarthy** ⊕ Erie, Pa.; Jefferson Medical College of Philadelphia, 1901; past president of the Erie County Medical Society; fellow of the American College of Surgeons; served during World War I; for many years surgeon for the Pennsylvania Railroad; affiliated with Hamot Hospital and St. Vincent's Hospital, where he died October 28, *aged 69, of coronary occlusion.*

**James Gibbons McGillicuddy,** Chelsea, Mass.; Albany (N. Y.) Medical College, 1909; served during World War I; for many years associated with the U. S. Public Health Service; died in the U. S. Marine Hospital, Boston, October 13, aged 64, *of arteriosclerosis and Parkinson's disease.*

**Donald Munro McIntosh,** Old Fort, N. C.; Medical College of Virginia, Richmond, 1904; member of the American Medical Association; past president of the McDowell County Medical Society; formerly councilor and president of the Tenth District of the Medical Society of the State of North Carolina; served during World War I; on the staff of Marion (N. C.) General Hospital; died October 29, aged 66, of cerebral hemorrhage.

**John Francis McKie,** Hot Springs, S. D.; Rush Medical College, Chicago, 1910; served during World War II; died in the Veterans Administration Hospital September 2, aged 65, of coronary occlusion and hypertension.

**Ray Randle Osborne** ⊕ Rockford, Ill.; Chicago College of Medicine and Surgery, 1912; affiliated with St. Anthony Hospital; *died October 24, aged 66, of cerebral embolism.*

**Hewell Coleman Samuel,** Sanatorium, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1941; *member of the American Trudeau Society;* assistant superintendent of the State Tuberculosis Sanatorium; died October 21, aged 35.

**Albert Spottke,** New York; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1887; died in White Plains, October 29, aged 87, of myocardial degeneration.

**Louis Joseph Thibault,** Waterbury, Conn.; Yale University School of Medicine, New Haven, 1900; served as school physician of Waterbury and health officer of Wolcott; on the staff of St. Mary's Hospital, where he died September 12, aged 70, of carcinoma of the prostate.

**Carl Samuel Jonathan Tillmanns** ⊕ Los Angeles; Washington University School of Medicine, St. Louis, 1907; an Associate Fellow of the American Medical Association; died in Inglewood, September 14, aged 65, of aortic stenosis.

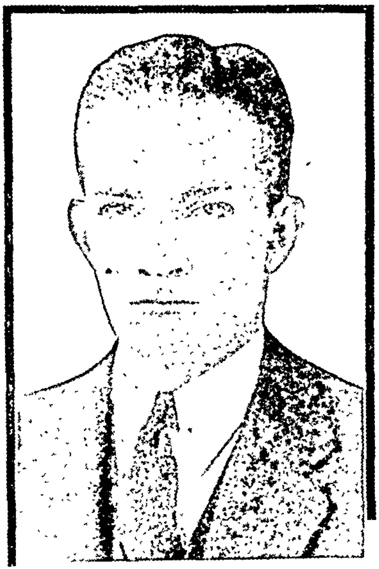
**Genevieve Tucker,** Livingston, N. J.; University of Michigan Homeopathic Medical School, Ann Arbor, 1880; died September 28, aged 89, of cardiovascular renal disease and *sarcoma of the left forearm.*

**Carl Christian Vogel,** Elroy, Wis.; Bennett Medical College, Chicago, 1901; Northwestern University Medical School, Chicago, 1903; died in the Richland Hospital, Richland Center, September 26, aged 74, of bronchopneumonia, paralysis agitans and arteriosclerosis.

**Frederick Paul White,** Lemongrove, Calif.; University of Louisville (Ky.) Medical Department, 1888; died in the Paradise Valley Sanitarium and Hospital in National City, October 30, *aged 84, of heart disease and hypertension.*

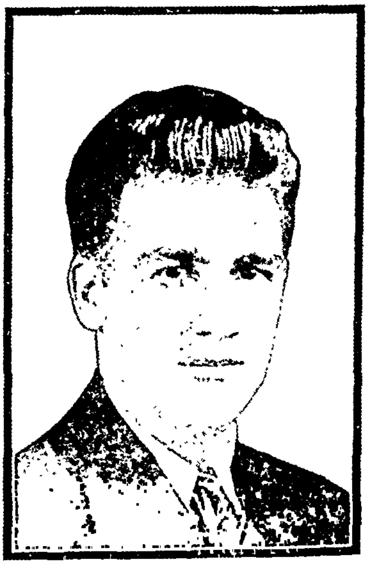
**Charles Edward Wooding** ⊕ Narberth, Pa.; University of Virginia Department of Medicine, Charlottesville, 1905; died October 5, aged 69, of coronary occlusion.

## KILLED IN ACTION



Lieut. Henry W. Hughes
M.C., A.U.S., 1906-1945

Capt. Abraham Sophian Jr.
M.C., A.U.S., 1915-1944



Capt. Norman E. Zahrt
M.C., A.U.S., 1915-1946

**Henry William Hughes,** New York; Georgetown University School of Medicine, Washington, D. C., 1933; member of the American Medical Association; interned at St. Vincent's Hospital; served a residency at the Central Islip State Hospital at Central Islip, N. Y.; began active duty as a first lieutenant in the medical corps, Army of the United States, in April 1942; in April 1943 was listed as a battle casualty and prisoner of war in Germany; killed in action in the European area March 31, 1945, aged 38.

**Abraham Sophian Jr.,** Kansas City, Mo.; Cornell University Medical College, New York, 1941; interned at the Mount Sinai Hospital in Cleveland; entered the medical corps, Army of the United States, as a first lieutenant *in July 1942; promoted to captain;* later transferred to the 507 Parachute Infantry Regiment; reported as missing in action June 11, 1944, in France; died in July 1944, aged 29.

**Norman Eldridge Zahrt,** Marengo, Iowa; State University of Iowa College of Medicine, Iowa City, 1941; interned and served a residency at the University Hospitals in Iowa City; began active duty as a first lieutenant in the medical corps, Army of the United States, in December 1942; promoted to captain; missing in action July 25, 1945; aged 30; determined dead July 26, 1946.

### Lord Horder's Criticisms of the National Health Service

Lord Horder, who is chairman of the Fellowship for Freedom in Medicine, has criticized the National Health Service in the lay press. He admits that as it has been in action only five months it is perhaps too soon to judge how much the patient on the one hand, and the doctor on the other, have gained or lost by the nationalization of medicine. Fortunately, the general health of the community has been high, which has kept the medical work low. In two matters the patient is feeling the pinch. One is the difficulty in getting his medicines without paying for them. The other is the sudden and considerable rise in the cost of beds in private hospital wards.

The citizen as taxpayer will have noted with some alarm that the estimated budget for the Service has been greatly exceeded. As regards the doctor, the defects stand out clearly. "Evidence is accumulating," says the secretary of the British Medical Association, "that the burden of work, particularly paper work, has greatly increased, that in many instances income has gone down; that private practice in many areas has virtually disappeared." Dr. Dain, chairman of the British Medical Association Council, repeats the dirge: "We have two difficulties—the demands on the doctors made by the patients and the insufficient pay for the doctors. We warned the Government that there was not the manpower in the medical profession or the nursing profession, nor the hospital beds available to implement the Service. Our warning was not heeded and now we are reaping the unfortunate consequences." The tragedy is that the precipitancy in nationalization was not halted by the British Medical Association.

The hundreds of letters received by the newly formed Fellowship for Freedom in Medicine show anomalies and obstructions. One doctor writes that the whole ethical basis of his daily work has been undermined. He has either to adhere to private work and suffer grave financial loss or else join the Service and take on more patients than he can look after adequately. At the moment he compromises by limiting the Service list, but the position is difficult and may not be tenable for long. Another doctor complains of grave financial loss. Both types of letter could be multiplied indefinitely. It may be said this is only the doctor's point of view. Lord Horder replies, "There is no such thing as only the doctor's point of view. Bureau or no bureau the basic element of any service must always be the doctor. The crass folly of not recognizing this and of assuming that personnel can be nationalized led to this colossal blunder. The essence of good doctoring is diagnosis, which calls for time and a close-up with the patient, both of which are now denied to thousands of practitioners. That a doctor cannot pay his way unless he has 4,000 possible patients on his list is as great a disservice to the public as to the medicine."

### Renewed Attempt to Establish a National Health Service in Australia

For some time the Australian Government, which is under the control of the Labor Party, has tried to introduce a National Health Service, but has been successfuly resisted by the medical profession. The Minister of Health has now introduced a new bill for the purpose. He explained that the measure merely outlines the services, details of which could be progressively developed by regulations. The Government did not contemplate, nor did the Constitution permit, any nationalization of doctors or dentists. It was proposed to establish advisory committees of these professions to exercise a real influence on the development of the scheme. A grave shortage of doctors and dentists, facilities and buildings made gradual development of the services inevitable. The bill enabled the Commonwealth to make grants to the Australian states and other authorities for the construction, improvement and equipment of hospitals and for the provision by the states of any national health service. The services to be provided included general, consultant, specialist, dental, maternal and child health services, aerial medical and dental services and diagnostic and therapeutic convalescent after-care and nursing. The bill also authorized establishment of a medical benefit scheme for the payment of a portion of the fee of doctors. The British Medical Association had been invited to act on the committee with Commonwealth officers to consider the schedule of fees and other problems, which involved no interference with the doctor-patient relation. The patient would visit the doctor in the usual way and on his advice go, if necessary, to the appropriate specialist, half of whose fee the Government would pay. The bill authorized all efforts of doctors to establish group practices and would establish health centers, corresponding to the offices of large medical partnerships, which would provide general practitioner, specialist and diagnostic facilities. The scheme would cost annually for doctors $24,000,000.

It will be noticed that the Australian scheme differs from the British National Health Service in that the patient has to pay half the specialist's fee, while in Britain he pays nothing. This is certainly an improvement, as it does somewhat reduce the evils of "something for nothing," which, as shown in previous letters to The Journal, is the root of many evils in the British National Health Service.

### Munificent Gift for Surgical Research and Education

London is becoming more than ever an international medical center. The latest development is due to the munificence of the automobile magnate Lord Nuffield, who has already done so much to promote medical research. He has now given $1,000,000 to the Royal College of Surgeons for the promotion of research and education in the surgical sciences and in order to increase facilities and amenities for young surgeons, particularly those from the British Dominions, the United States and other countries who come to Britain for advanced study. The donor feels that if the Royal College of Surgeons is to make the fullest use of its facilities it is desirable to have residential accommodation on its own site, so that graduates who are studying surgery and the basic sciences in London may have access at all times to the unique museums, the library and the laboratories of the college. The donor also strongly believes in the beneficial influence of collegiate life. His gift is to be devoted to erecting a College of the Surgical Sciences attached to the Royal College of Surgeons, where the students will be able to live, to meet socially the principal surgeons of this country who will be attending the college and also distinguished surgical teachers from other countries, who will naturally use the college during their visits to London. It will be known as the Nuffield College of Surgical Science.

The donor is hopeful that those who have the privilege of living in the college and those who use its amenities will be imbued with something of the spirit of the collegiate life of the older residential universities, and that they will make contacts with leaders of their profession, which will be a stimulus to them and their own pupils throughout their lives, however many thousand miles they may be away from London, to the ultimate benefit of all in need of surgical aid throughout the world.

### Distillate of Cod Liver Oil, a Powerful Antibiotic

J. Solomides discovered in 1946 that the product of distillation of cod liver oil is an antibiotic strongly bactericidal. Experiments in vitro show that microbes in contact with this distillate die hundreds of times more quickly than do microbes in contact with cod liver oil.

| | Cod Liver Oil, Minutes | Distillate, Minutes |
|---|---|---|
| Colibacillus | 360 | 0.5 |
| Staphylococcus | 360 | 0.5 |
| Bacillus tuberculosis | 2,800 | 10 |

Experiments on guinea pigs have confirmed the antibiotic power of this product. The author has made the first therapeutic trials with local application of the distillate in pure form or incorporated in an excipient with a petrolatum or wool fat base, in microbic or amicrobic dermatitis. Results were excellent and rapid in 3 cases of furuncle, some cases of acne, 4 cases of onychomycosis and 5 cases of mycosis. The author has obtained recoveries in 7 of 10 cases of chronic eczema, in 3 cases of burns of the second degree and 2 roentgen ray burns. The author has been struck by the antiphlogistic and soothing effect of this product, its composition being 82 per cent fatty acid and 18 per cent nonsaponifiable substances; the former may be endowed with a vitaminic F activity, which could account for the action on eczema and pruritus.

J. Cabibel has studied the effect of this distillate in certain conditions associated with adenopathy or other tuberculous symptoms, which Burand, Dejean, Jaquelin and others consider as pretuberculous or atypical tuberculosis. Treatment is 0.10 Gm. distillate of cod liver oil given in suppositories every four to five days for three to four weeks. In 50 per cent of the cases, the treatment has been effective, sometimes in a spectacular way; in 25 per cent improvement was less noticeable, and in 25 per cent it was still inapparent after the administration of eight to ten suppositories. In 1 of 2 cases of typical tuberculosis the treatment has proved satisfactory after three months.

### Meeting of Experts on Plague and Typhus

Under the auspices of the International Office for Public Hygiene and of the World Health Organization a meeting took place in Paris October 5-8, to promote an international campaign against plague and typhus. The discussion was conducted by Dr. Gaud, director of the office; Dr. Y. Biraud, director, Division of Epidemiology, World Health Organization, acted as secretary; others taking part were Dr. G. Blanc, director of the Pasteur Institute of Morocco, and Dr. A. Macchiavello, epidemiologist of the Panamerican Sanitary Office, Lima, Peru. The report drawn by these scientists shows that: (1) it is possible to eliminate all danger of plague in villages and towns thanks to D.D.T. (dichlorodiphenyltrichloroethane) and to certain poisons against rats; (2) plague among rodents, living far away from human communities escapes all control, but does not constitute a serious danger to man; (3) the use of living vaccines in Africa and Java (15,000,000 persons have been vaccinated) proved effective for the prevention of plague, but vaccination can play only a secondary part, rats being transmission agents of the disease; (4) according to experts, in many cases formerly considered fatal, cure can be effected today with streptomycin and sulphonamide compounds; (5) D.D.T. also plays a part of prime importance in the prevention of typhus; (6) remarkable results in the treatment of typhus were obtained with an antibiotic similar to streptomycin, the existence of which has been brought to light by recent studies made in South America.

### Larger Venous Grafts Successful

In 1920, Professor R. Leriche attempted to replace segments of arteries affected with thrombosis by venous graft. At that time numerous attempts were not entirely successful except when the graft did not extend over 5 to 6 cm. Larger grafts were considered impracticable on account of the risk of provoking a new thrombosis. Recently J. Kunlein, one of the disciples of Leriche, resumed this method, using the anticoagulative power of heparin, and he has performed venous grafts of 15, 26, 28 to 29, 34.5, 35.5, 37 and 47 cm. in 8 patients seriously affected and whom vasodilator methods did not improve sufficiently. The results, presented at the last meeting of the National Academy of Sciences by Professor Leriche and Dr. Kunlein, were excellent: Once the graft is performed, blood circulates freely, the peripheral pulse reappears, the foot gets warm again and pain disappears. Seven grafts out of 8 have remained permeable, among which is a 37 cm. graft of five months' duration, another of three months and others of only a few weeks. Patients operated on have resumed walking without claudication, which is the great advantage over arteriectomy. It is the first time that venous grafts of such length have been realized without alteration of the venous endothelium in 7 cases out of 8. The authors think that this new method will transform the future of patients affected with arterial thrombosis.

FLORENCE, Nov. 15, 1948.

### Semb's Thoracoplasty

At a meeting of the Association Against Tuberculosis in Genoa, Prof. Biancalana presented a report of Semb's thoracoplasty, an operation frequently done in the Anglo-American countries, but little known in Italy. The speaker gave an exact description of the operative technic and particularly of the apicolysis. The exposure is obtained along the mediastinal fascia instead of by the extrapleural route. The intervention described by Semb in 1935 consisted of the removal of five to six ribs in one stage. Resulting complications were frequent, due to massive caseous pneumonia or aspiration bronchopneumonia, particularly in phrenectomized patients, who have difficulty in expectoration. Lobar or total atelectasis was frequent, which prepared the ground for pneumonia. These complications induced Biancalana in 1940 to carry out the intervention in two stages, generally with the removal of three ribs in each stage. Criticism, starting with the subdivision of the intervention into several stages, that the patient may present himself the second time in worse condition, that the resection of the ribs must be more extensive and that the infectious complications may be greater, does not seem well founded according to Biancalana's experience. Neither does the speaker share the conviction of some surgeons that the cavities, being pushed back by the apicolysis toward the elastic parenchyma, may be less easily collapsible than those pushed against the rigid floor of the vertebral bodies and the mediastinum, as in simple plastic operations. The speaker has observed suppuration of the operative breach in only 2 or 3 per cent of the cases. Occasionally a rise of temperature makes one think of an infection of the sero-hemorrhagic collection in the cavity of the apicolysis. In those cases Biancalana omits an explorative puncture because of the risk of spreading infection to an area where it did not exist, and he does not advise maintaining drainage for the first twenty-four hours as Semb does, since he believes the extravasation useful for maintenance of the collapse of the apex. Biancalana concluded that the distrust in this intervention is not justified. In fact in his cases the mortality rate was 3 per cent, while in 79 per cent of the cases he obtained good results or stabilization. In only 18 per cent did he observe doubtful results or failures.

### Congress of the Latin Otorhinolaryngologic Association

This association held its seventh congress in Turin Sept. 20-22, 1948, dealing extensively with the subject of the palatine tonsil.

Terracol and Guerrier reported on the blood supply of the tonsils. Bachi reported on the embryology of the palatine tonsil. Taillens discussed tonsillar physiopathology. Porta reported on the changes in the tonsil at various ages. In the third, the fourth and the fifth decade the pavement epithelium which covers the free part of the tonsil presents two types of cell described by Agazzi; i. e., corneal pearls and epithelial bodies which reveal a morphologic and structural analogy with Hassal's corpuscles in the thymus. Mottura reported on the hyperplastic and neoplastic phenomena associated with the lymphoreticular tissue of the tonsil. Cambrelin spoke about tonsillar manifestations in the pathology of leukemia, aleukia and lymphogranulomatosis.

### Cortical Secretion and the Defense of the Organism

Dr. Morros Sarda, professor of physiology at the Escuela Española de Veterinaria, has done important studies on cortical secretion. He is a pupil of Dr. G. Marañón and his work was accomplished under the auspices of the school mentioned. The author found experimentally that there is a basic secretion of cortical hormones which, in certain circumstances, is increased, through intervention of the corticotropic hormone of the hypophysis. Because of the difficulties of determining the cortical steroids in the blood and urine, the author followed the methods of Long, Lowenstein and Zwemer for determining the values of cholesterol and of ascorbic acid in the blood, the changes in which values are reliable as representing the values of the cortical secretion. High values of ascorbinemia and of cholesterolemia are observed in all diseases corresponding to Selye's syndrome. They show cortical hypersecretion stimulated by corticotropic hormone. The initial reaction in these circumstances seems to be the secretion of epinephrine, as previously suggested by Cannon. In normal dogs weighing between 12 and 15 Kg., an injection of epinephrine in a dose varying between 0.1 and 0.4 mg. provokes an increase of blood sugar, blood cholesterol and blood ascorbic acid within the first one to two hours after the injection. That is the same response obtained to the injection of corticotropic hormone, which response seems to indicate that the medullary hormone provokes the discharge of the cortex through the hypophysis. This interpretation will be substantiated by experiments which are under way on hypophysoprivic animals. These results agree with those reported by Long on the effect of epinephrine in lowering the amount of cholesterol and ascorbic acid in the adrenal glands, probably because of the immobilization of both substances.

Studies are also under way to ascertain the changes of the blood of normal dogs after injection of large doses of either whole cortical extract or desoxycorticosterone acetate. They include refractometric quantitative determinations of the albumins and globulins of the blood and the changes of blood proteins after the injection. It has been proved that the injection of whole cortical extracts causes an increase of the proteins of the blood at the expense of the globulin fraction, the increase being associated with an increase of the speed of sedimentation of the erythrocytes and more or less lymphopenia. These results agree with those of White and collaborators. The changes caused by the injection of desoxycorticosterone acetate are of the same order.

A "syndrome of alarm" has been provoked in normal dogs by administering an intraperitoneal injection of saline serum near the freezing point. Study of the blood (leukocytic formula, sedimentation rate, albumins, globulins, glycemia, ascorbic acid and cholesterol) yields data similar to those obtained by the direct injection of either the corticotropic principle or the whole extract of the cortex. It is possible, as White suggested, that the increase of globulins is due to lympholysis with consequent liberation of gamma globulins.

The intraperitoneal injection of cold saline serum to splenectomized animals causes the same changes in their blood as it does in normal animals. These results do not confirm the point of view of Ungar, who believes that the spleen intervenes in the reaction of alarm by means of the production of "splenine" (a spleen substance).

The changes of ascorbic acid in the blood of normal or adrenalectomized rats were ascertained after intraperitoneal injection of either saline serum or epinephrine. These experiments were done on rats because these animals survive the operation if they are given salt in the water they drink and the technic of adrenalectomy in rats is simple. Because the amount of blood necessary to determine the level of ascorbic acid in the blood cannot be obtained from the same animal, rats from different lots were used. All the animals were kept on the same diet and were of about the same weight when they were used. The values of ascorbic acid in the blood of normal rats (first lot) which were killed for this determination were considered as basal values. Normal rats in the second and third lots had an injection of epinephrine and were killed one and two hours, respectively, after the injection of epinephrine. The values of ascorbic acid in the blood of rats of the second lot were higher than those of rats of the third lot, which in their turn had higher values than those of rats in the first lot.

The blood levels of ascorbic acid in adrenalectomized rats are not modified by the administration of an injection of epinephrine. The intraperitoneal injection of very cold saline serum induces changes in the blood levels of ascorbic acid in normal rats but not so in adrenalectomized rats. The results support the belief of the intervention of epinephrine in the development of the syndrome of alarm, giving origin to the consecutive intervention of corticotropic hormone and further occurrence of cortical secretion.

In animals into which a large amount of cortical extract is injected before they are subjected to the stimulus provoking the reaction of alarm, the changes of the blood in the course of the syndrome are almost unnoticeable (the ascorbic acid level in the blood frequently does not change). This fact, which was previously reported by the Sayers, suggests that in these circumstances there is neither a secretion of the corticotropic principle nor a subsequent cortical reaction. The fact shows that the secretion of the corticotropic principle is conditioned by a certain level of cortical hormones or cortical principles in the blood. If the latter diminishes, as probably happens in animals not previously treated, and subjected to the stimuli which produce the syndrome of alarm, the latter will occur in the presence of a diminished level of the hypophysial principle, with consequent mobilization of cortical steroids together with ascorbic acid and cholesterol. In animals previously treated, the exogenic cortical hormone prevents lowering of this substance in the blood and the consequent hypophysial reaction. This also occurs with either the thyroid hormone or the estrogens, the lowered concentration of which in the blood causes hypersecretion of the correspondent glandulotropic principle.

The results of these experiments show that the body consumes a large amount of cortical hormones in the conditions created by the syndrome of alarm. They seem to place some value on the role of epinephrine in stimulating secretion of cortical hormones, which is regulated by the level of these hormones in the blood. Lowering of the level will stimulate secretion and liberation of the corticotropic principle, whereas an increased level will delay secretion. It is possible, however, as Long suggested, that epinephrine is the cause of the consumption of cortical hormone by the tissues through the metabolic changes which it produces.

The authors believe that the chain of facts is as follows: stimulation of the sympathetic nervous system with consequent discharge of epinephrine; consumption of the cortical hormone in the blood by the tissue, through the metabolic changes due to the effect of epinephrine; lowering of the cortical hormone in the blood and discharge of the corticotropic principle; discharge of adrenal cortical secretion together with secretion of ascorbic acid and of cholesterol, and increased amount of ascorbic acid and cholesterol in the blood, lymphopenia, lympholysis, liberation of lymphocytic proteins and increase of proteinemia at the expense of the fraction of globulins.

## Correspondence

### EPILEPSY IN CHILDHOOD

*To the Editor:*—In the December 4 issue of The Journal, page 1012, Dr. M. G. Peterman in an article "Epilepsy in Childhood" speaks disparagingly of "learned authorities" who "offer false encouragement and lead to cruel disillusionment" by speaking of "83 per cent improvement in epilepsy and of the 'hopeful disorder.'"

However, Dr. Peterman must himself be one of these "noted authorities," because in this same paper he presents data showing that 80 per cent of his patients given either phenobarbital or the ketogenic diet were improved. Presumably he still further increased this percentage by giving unimproved patients other drugs now available, diphenylhydantoin sodium ("dilantin sodium"), methylphenylethyl hydantoin ("mesantoin"), trimethadion ("tridione") or "thyphenytoin" (5,5-phenylthienylhydantoin).

When speaking to panic-stricken parents about epilepsy or other serious illnesses, must we avoid the word "hopeful" unless we can expect improvement in more than 80 per cent of patients? Must we remain gloomy until the proportion is 90 per cent, or, perhaps, 100 per cent?

William G. Lennox, M.D., Boston.

[Note.—The letter was referred to Dr. Peterman, who replies:]

*To the Editor:*—I may have spoken disparagingly of the misinformation given to the public by the "learned authorities" in the advertising of the medical journals.

One of these advertisements reads "equal opportunities for the child with petit mal! the opportunity to develop his natural aptitudes . . . to grow up with other children—like other children . . . to have full control of symptoms . . . this is ————'s answer to a high percentage of petit mal victims and their anxious parents."

The advertisements, and particularly the article in the *Saturday Evening Post,* imply that epilepsy may be cured. The public has so interpreted the article; hence, the criticism which I presented in my article. I am basing my conclusions on the correspondence and telephone calls I received after the publication of the article. I do not believe that a percentage reduction in the number of seizures means improvement as long as convulsions continue at least once a month and may be anticipated at any time.

You will note that in my article and in all of the others I have never used the word "cure." I have reported my results as they have been collected from my records by my assistants and me. This series is not large enough to justify conclusions and therefore they were not drawn.

When I speak to "panic-stricken parents" I try to give them the honest facts and the truth of the situation concerning the case in hand. I do believe that these parents may be given all the hope possible. They should be encouraged in every way. However, that does not mean to go to the length of advertising such statements as "83 per cent improvement" or that "epilepsy can be licked."

I would quite agree with Lennox and the Gibbs in their article in The Journal, Sept. 9, 1939, page 1002, in which they conclude after making tracings on 138 parents that "definitely abnormal records were obtained in 54 per cent of the relatives, against 6 per cent in a control group who were unrelated to epileptic persons. In forty-six of the families, records were made of both parents. In 28 per cent both parents and in 94 per cent at least one parent had abnormal records. We believe that this evidence indicates that the dysrhythmia of epilepsy is inheritable and such a dysrhythmia when demonstrable may represent a predisposition to epilepsy or some allied disorder.

"These observations should be of practical value in the prophylaxis and eugenics of epilepsy and should assist the physician in tracing the descent of epilepsy and in advising patients and their relatives about marriage."

That is exactly what I should like to do in the message that I believe should be given to the public. While this disease may not be inherited any more than diabetes, my point is that it is inherited as is diabetes and that the answer for its elimination lies in eugenics and birth control.

M. G. Peterman, M.D.,
411 E. Mason St., Milwaukee 2, Wis.

### THE DOCTOR AND WORLD PEACE

*To the Editor:*—We should like to emphasize that the greatest problem in preventive medicine today is the preservation of peace. In order to achieve a lasting peace, we feel that the extension of the principle of law and order to the world level is the only method that will work. To this end, it is necessary that the United States officially propose that the United Nations be strengthened sufficiently to enforce peace, and that the charter of the United Nations be amended for this purpose.

There are apparently three courses open: an indefinite armed truce, a third world war and world government. Opinion in favor of world government is growing rapidly in the United States and throughout the world. We do not know whether or not Russia will join in a world government. The only way to find out is to make the proposal. The United States can lose nothing by making such a sincere proposal and the whole world stands to gain immeasurably by such action.

Since the establishment of a durable peace would be the greatest measure ever undertaken in preventive medicine, we urge our fellow physicians to join and support their local chapters of the United World Federalists and we ask the House of Delegates to endorse the principle of extending enforceable law and order to the world level.

Edward Bortz, M.D.,
Past President of the American Medical Association and member of Advisory Board of Philadelphia Area Council of United World Federalists.

John Arnett, M.D.,
Member of the Philadelphia Area Council of United World Federalists.

Horace Pettit, M.D.,
President, United World Federalists of Pennsylvania.

# Miscellany

## RECOMMENDED TERMS AND DEFINITIONS FOR CELLS OF THE LEUKOCYTIC, ERYTHROCYTIC AND THROMBOCYTIC SERIES

The Committee for Clarification of the Nomenclature of Cells and Diseases of the Blood and Blood-Forming Organs, sponsored by the American Society of Clinical Pathologists and the American Medical Association, has prepared two reports[1] of its recommendations for preferred hematologic terminology which are briefly summarized in the present report. It is not the intention of the committee to imply from its recommendations of terms to be used that the origin of all these cells has been settled. No changes are suggested in the criteria in current use for determining the series to which a cell belongs. It is planned that a permanent body should reexamine the terms periodically, perhaps every five or ten years.

The present report consists of general terms which are recommended, followed by a list summarizing the names for each

### *Terms To Be Used and Terms To Be Avoided*

(The essential characteristics which distinguish each stage of development from the preceding and following ones are given in italics above and below the arbitrary lines of demarcation.)

| Term To Be Used | Terms To Be Avoided |
|---|---|
| **Lymphocytic Series** | Lymphoid, lymphatic, lymphogenous, lymphocyte, mononuclear |
| Lymphoblast<br>*Fine chromatin structure* | Myeloblast, hemocytoblast, lymphoidocyte, stem cell, lymphocyte |
| *Chromatin clump*<br>Prolymphocyte<br>*Larger cell size or finer chromatin* | Large lymphocyte, pathologic large lymphocyte, atypical leukocytoid lymphocyte, monocyte, immature lymphocyte |
| *Coarse chromatin structure*<br>Lymphocyte | Small, medium or large lymphocyte, normal lymphocyte, small medium or large mononuclear |
| **Monocytic Series** | Monocytoid, monocytogenous, mononuclear, monocyte |
| Monoblast<br>*Fine chromatin structure* | Myeloblast, hemocytoblast, lymphoidocyte, lymphocyte, stem cell, immature monocyte |
| *Irregularly shaped nucleus*<br>Promonocyte<br>*Nucleolus present* | Premonocyte, hemohistioblast, immature monocyte, Ferrata cell |
| *Nucleolus absent*<br>Monocyte | Large mononuclear, transitional, clasmatocyte, endothelial leukocyte, histiocyte, resting wandering cell |
| **Granulocytic Series** | Myeloid, myelogenous, myelocyte, myelocytic, granulocyte, leukocyte, leukocytic, leucocyte, leucocytic |
| Myeloblast<br>*Fine chromatin structure* | Granuloblast, hemocytoblast, lymphoidocyte, lymphocyte, stem cell |
| *Chromatin clump*<br>Progranulocyte<br>*No specific granules* | Promyelocyte II, leukoblast, myeloblast, premyelocyte, promyelocyte, progranulocyte A |
| *Specific granules*<br>Myelocyte<br>*Round or oval nucleus* | Granulocyte, myelocyte B, non-filament, class I |
| *Indented nucleus*<br>Metamyelocyte<br>*Bean or kidney shaped nucleus* | Metagranulocyte, juvenile, myelocyte C, nonfilament, class I |
| *Part of nucleus with parallel sides*<br>Band cell<br>*No filament present* | Staff cell, stab cell, non-filament, class I, rod nuclear, polymorphonuclear, stabkernige, rhabdocyte, non-segmented |
| *Nuclear lobes connected by filaments*<br>Segmented cell | Polymorphonuclear, filamented, class II, III, IV or V, lobocyte |
| **Plasmacytic Series** | Plasma cellular, plasmacytogenous, myeloma cell, plasmacyte |
| Plasmablast<br>*Fine chromatin structure* | Myeloblast, hemocytoblast, lymphoidocyte, lymphocyte, stem cell, lymphoblastic plasma cell, myeloma cell |
| *Chromatin clump*<br>Proplasmacyte<br>*Nucleolus present* | Türk cell, Türk irritation form, lymphoblastic or myeloblastic plasma cell, myeloma cell |
| *Nucleolus absent*<br>Plasmacyte | Plasma cell, Unna's plasma cell, Marschalko's plasma cell, plasmacytoid lymphocyte, myeloma cell |
| **Erythrocytic Series** | Erythroid, erythrocytoid, erythron, erythrocytogenous, erythrocyte |
| Rubriblast<br>*Fine, stippled chromatin* | Erythroblast, megaloblast, pronormoblast, promegaloblast, normoblast, hemocytoblast, stem cell, myeloblast, lymphoidocyte, karyoblast |
| *Chromatin clump*<br>Prorubricyte<br>*Nucleolus present* | Erythroblast, megaloblast, pronormoblast, normoblast, macronormoblast, macroblast, prokaryocyte |
| *Nucleolus absent*<br>Rubricyte<br>*Definite chromatin structure* | Normoblast, pronormoblast, macronormoblast, erythroblast, polychromatophilic normoblast, karyocyte |
| *Pyknotic nucleus*<br>Metarubricyte<br>*Nucleus present* | Normoblast, erythroblast, metakaryocyte |
| *Nucleus absent*<br>Reticulocyte<br>*Reticulum present with supravital stain* | |
| *No reticulum*<br>Erythrocyte | Red blood cell, erythroplastid, normocyte, akaryocyte |
| **Thrombocytic Series** | Megakaryocytic, platelet, thrombocyte |
| Megakaryoblast<br>*Fine chromatin structure* | Megalokaryoblast |
| *Chromatin clump*<br>Promegakaryocyte<br>*Nucleolus present* | Premegalokaryocyte |
| *Nucleolus absent*<br>Megakaryocyte<br>*Nucleus present* | Megalokaryocyte |
| *Non-nucleated cytoplasmic fragment*<br>Thrombocyte | Platelet, thromboplastid |

[1] First report of the Committee for Clarification of the Nomenclature of Cells and Diseases of the Blood and Blood-Forming Organs. Am. J. Clin. Path. **18**: 443-450, May, 1948. Second report of the Committee for Clarification of the Nomenclature of Cells and Diseases of the Blood and Blood-Forming Organs, (to be published).

series and for the individual cells, showing the number of stages of differentiation which are of clinical significance, giving clear-cut criteria for the exact point of arbitrary differentiation between stages, and names previously in use, which it is recommended be avoided so that clarity can be attained in hematologic literature and reports.

### Miscellaneous Definitions

*Leukocyte:* Any white blood corpuscle or its precursor.

*Blast Cell:* The most undifferentiated cell of any series, having fine chromatin structure, usually demonstrable nucleoli and basophilic cytoplasm with or without azurophilic granules.

*Fine Chromatin Structure:* A nuclear appearance of a background of homogeneous lighter-staining parachromatin, overlaid by a darker-staining lace net meshwork or finely stippled pattern of basichromatin with no aggregation of the basichromatin into even a single clump of appreciable size.

*Nucleolus:* A homogeneous blue-staining area in the nucleus, staining more like the cytoplasm of the cell.

*Azurophilic Granules:* The granules seen typically in monocytes and lymphocytes. The term refers to an affinity for a particular dye and not to the color or the granules.

*Specific Granules:* Neutrophilic, eosinophilic or basophilic granules.

*Granulocytes:* An inclusive term to apply to cells containing ecific granules, regardless of stage of differentiation.

*Disintegrated Cell:* Any cell of any series in which the cyto-asmic outline or nuclear membrane has been disrupted, exclud-g changes that occur during mitosis. They should be recorded all differential reports.

*Pernicious Anemia Type:* The qualifying adjective phrase to applied to any cell of the erythrocytic or granulocytic series indicate the presence of morphologic changes characteristi-lly seen in pernicious anemia and certain other macrocytic emias. This change is a relative increase of parachromatin nucleated erythrocytes and giant forms with bizarre nuclei in the granulocytes.

Modifying adjectives may be applied to any of the recommended terms but their definitions should be clearly stated in all publications and reports.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc.: *Written.* July 15. Various locations. Final [illegible] is April 15. Sec., Dr. Curtiss B. Hickcox, [illegible] York 27.

American Board of Dermatology and Syphilology: *Written.* Various Centers, Feb. 17. *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: *Oral.* San Francisco, Feb. 8-10, 1949. New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Final date for filing application is Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Written.* Jan. 14. *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part I.* Various Centers, April and May. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* St. Louis, Feb. 18-20. Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry and Neurology: *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska:* Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

Arkansas:* Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 2-3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination,* Los Angeles, Feb. 28-March 3. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

Connecticut:* *Hartford, March 8-9.* Secretary to the Board, Dr. Creighton Barker, 258 Church Street, New Haven.

District of Columbia:* *Reciprocity,* Washington, March 14. Sec., Dr. George C. Ruhland, 4130 Municipal Building, Washington.

Florida:* *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif.

Indiana: *Examination.* Indianapolis, June. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Maine: Portland, March 8-9. Sec., Dr. Adam P. Leighton, 192 State Street, Portland.

Maryland: *Examination,* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore.

Massachusetts: *Examination. Boston, March 8-11. Sec., Dr. George* L. Schadt, 413 E. State House, Boston.

Minnesota:* Minneapolis, Jan. 18-20. Sec., Dr. J. F. DuBois, 230 *Lowry Medical Arts Building, St. Paul.*

Mississippi: Jackson, June. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Missouri: *Kansas City, Jan. 24-26.* Sec., Mr. John A. Hailey, State Capitol Bldg., Box 4, Jefferson City.

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

Nebraska:* *Examination.* Omaha, June. Dir., Bureau of Examining *Boards, Mr. Oscar F. Humble, 1009 State Capitol Building,* Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Hampshire: Concord, March 10. Sec., Board of Registration in Medicine, Dr. John S Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: *Santa Fe, April 11-12.* Sec., *Dr. V. E. Berchtold,* 141 Palace Ave., Santa Fe.

New York: *Examination.* Various Centers, Feb. 1-4. Sec., Dr. J. L. Lochner, Jr., 23 S. Pearl St., Education Bldg., Albany.

North Carolina: *Endorsement.* Raleigh, Jan. 17. Sec., Dr Ivan M. Procter, 226 Hillsboro St., Raleigh.

Ohio: *Endorsement.* Columbus, Jan. 25 and April 5. *Written.* Columbus, June. Sec., Dr. H. M. *Platter, 21* W. Broad St., Columbus.

Pennsylvania: *Examination.* Philadelphia, Jan. 1949. Act. Sec., Mrs M. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: *Examination.* Santurce, March 1. Sec., Mr. *Luis Cueto* Coll, Box 3717, Santurce.

South Carolina: Columbia, June 27-29. Sec., Dr. N. B. Heyward, *1329 Blanding St., Columbia.*

South Dakota:* Pierre, Jan. 18-19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

Texas: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Vermont: *Examination.* Burlington, Feb. 3-5. Sec., Dr. F. J. Lawliss, Richford.

[illegible] Jan. 17-19. Sec., Dept of Licenses, Miss [illegible] npia.

[illegible] Cheyenne, Feb. 7. Sec., Dr. Franklin D. [illegible]

---

* *Basic Science Certificate required.*

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1931, Juneau.

Colorado: *Examination.* Denver, Mar. 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Connecticut: New Haven, Feb. 12. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., *New Haven 10.*

District of Columbia: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

Florida: *Examination. Gainesville, June 11.* Sec., *Mr. M. W. Emmel,* University of Florida, Gainesville.

Minnesota: *Examination.* April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, March 5 and June 18. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Rhode Island: *Examination.* Providence, Feb. 9. Chief, Mr. Thomas B. *Casey, 366* State Office Building, Providence.

South Dakota: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

Tennessee: Memphis, March 21-22. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Wisconsin: Madison, April 2.. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Food and Drug Acts: Sufficiency of Evidence of Misbranding.**—The Pasadena Research Laboratories, Inc., and an individual defendant were found guilty on five counts of an information charging that they unlawfully introduced adulterated and misbranded drugs into interstate commerce. From judgments fining the laboratory and placing the individual defendant on probation, all the defendants appealed to the United States court of appeals, ninth circuit.

Two drugs manufactured by the defendants were involved in this proceeding. The first was known as "indoform," vials of which carried labels announcing that each cubic centimeter thereof contained three "international units" of posterior pituitary and 1 grain of "thyroid substance." A vial of this drug was sent to the office of the Food and Drug Administration in Washington, D. C., and was there examined by a pharmacologist and analyst employed by the Administration. He testified that he "found practically no posterior pituitary in that product, an almost immeasurable quantity." After conducting the test, he placed the bottle into a locked refrigerator until the next day, when he wrapped it, put a seal on it and sent it to San Francisco. He was asked whether or not the drug had contained 3 international units on the date of shipment by the defendant some six months previously, and he answered that it was his opinion that on the date in question "there was a quantity of posterior pituitary which was not measurable by the standard methods of measuring it, or there was none." When the drug reached San Francisco it was examined by a chemist for the Administration located in that city, who tested the drug for "thyroid content." He testified, "There was no thyroid present whatsoever."

The other drug was known as "pluri-B." The labels on vials of this drug set forth that this "sterile solution of pluri-B" contains 50 mg. of thiamine hydrochloride per cubic centimeter. The labels also said that the contents were "for intramuscular or intravenous use." A chemist in the employ of the Administration in Washington, D. C., examined vials of this drug and testified that he found it contained approximately 33 mg. per cubic centimeter. Other vials of this drug were examined by the chief of the chemical section of the medical division of the Administration who held a doctor's degree in biochemistry. He testified that he put the vials up to a light and found "with the naked eye" that all six of them "were very badly contaminated with undissolved material." He also testified, ". . . from experience with these materials and from general information of so-called supersaturated solutions, of which this is an example, I would say that this undissolved material was undoubtedly present on June 18 when the material was shipped."

In discussing the many contentions raised by the defendants on appeal, the court of appeals said, among other things, that, while the defendants professedly recognize the rule that the government must prove its case beyond a reasonable doubt, their briefs are replete with expressions which seem to indicate that in reality the standard actually insisted on is that the government's evidence should remove all possible doubt. Quoting from a prior United States circuit court of appeals case, the court said, "The proof in a criminal case need not exclude all doubt. If that were the rule, crime would be punished only by the criminal's own conscience, and organized society would be without defense against the conscienceless criminal and against the weak, the cowardly and the lazy who would seek to live on their wits. The proof need go no further than reach that degree of probability where the general experience of men suggests that it has passed the mark of reasonable doubt."

The defendants also contended that the opinions of the government's witnesses, based on tests made after the drugs had been shipped to Washington, were "absolutely worthless because the expert witnesses had no knowledge that the alleged adulteration or misbranding did not occur enroute to the doctor's office, or in the doctor's office, or in the hands of the Government inspectors who picked up the drugs, or enroute to Washington, D. C., when shipped there by the Government inspectors." Carried to its logical conclusion, said the court of appeals, this "chain of possession" theory would require the government to prove affirmatively that each one of the many mail clerks, administration clerks and experts, doctors, nurses, express company employees "and others" handled and cared for the goods so that changes could not occur while the drugs were in their custody. Such a rigorous exaction regarding proof is supported neither by reason nor by authority. In fact, the court concluded, "There is no such rule and never has been." There is a presumption that private persons do their duty and exercise due care and this presumption should apply also to doctors and nurses whose professional training and traditions teach them to be meticulous in the handling of preparations that are to be administered to their patients. The defendants, said the court, have not pointed out, nor have we been able to find, a scintilla of evidence in the record to indicate that any of the vials were mishandled by a single postal clerk, expressman, doctor, nurse, government analyst, administration mail clerk, or any one else who had any connection with the sealing, labeling, consignment, transmission, unwrapping, unsealing or testing of the products in question. The only suggestions of mishandling are in the form of dire possibilities conjured up by resourceful counsel. On the basis of a careful study of the entire record in this case the court of appeals finally concluded that no error had been committed in the trial court and that the judgment against the defendants should be affirmed. (Certiorari denied by U. S. Supreme Court.)—*Pasadena Research Laboratories, Inc. v. United States, 169 F. (2d) 375 (1948).*

**Chiropractic Practice Acts: Board may not Waive Basic Science Act Requirements.**—The defendants, constituting the State Board of Chiropractic Examiners, were charged with issuing a certificate to practice chiropractic without being presented with a certificate of ability in the basic sciences. From a judgment of guilty, they appealed to the Supreme Court of Arkansas.

The chiropractic practice act of 1921 authorized the board to grant reciprocity "with States having equally as high literary professional requirements as provided in this State." The license seeker must also have graduated from a reputable college of chiropractic teaching a resident course of not less than three years in anatomy, chemistry, physiology, hygiene, symptomatology, chiropractic principles and diagnosis. An applicant meeting these requirements was granted a certificate to practice chiropractic in Arkansas without having first presented a certificate of ability in the basic sciences. The defendant argued that the chiropractic board is expressly empowered to recognize a reciprocating state's license because there has been a determination that the applicant was qualified in basic science subjects and that such state exacted literary professional requirements equal in dignity to those established in Arkansas. In 1929, however, the legislature established a board of basic science examiners. Section 19 of the basic science act directs that none of its provisions shall be construed as repealing any statute in force at the time of its passage "with reference to the requirements governing the issuing of a license to practice the healing art or any such branch thereof."

We think, said the supreme court, that the basic science act "superimposed [its] requirements" on preexisting laws. Since it directs how the licensing authority should proceed and is complete in this respect, construction is not difficult. Section 1 bars from examination any person who has not presented to the licensing board a certificate of ability in the basic science subjects issued by the state board of examiners [in the basic sciences]; but that board, Section 8, may waive the examination required by Section 7 and issue a certificate on which the licensing board may act. In either event the basic science board must certify. In the instant case the basic science board did not certify. Accordingly the judgment of guilty was affirmed. *Lindquist v. State, 213 S.W. (2d) 895 (Ark., 1948).*

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American J. Obstetrics and Gynecology, St. Louis

56:409-616 (Sept.) 1948. Partial Index

Further Follow-Up Study of Eclampsia. L. C. Chesley, W. H. Somers and F. H. Vann.—p. 409.
Sulfadiazine and Penicillin Prophylaxis in Cesarean Section. R. G. Douglas and R. Landesman.—p. 422.
Gynecologic Surgery in the Elderly with Special Reference to Risks and Results. F. D. Zeman and A. M. Davids.—p. 440.
Pregnancy and Kyphoscoliotic Heart Disease. C. L. Mendelson.—p. 457.
*Application of Silver Carbonate Stain for Diagnosis of Uterine Cancer by Vaginal Smear Method. H. S. Yue, G. M. Riley, N. F. Miller and K. Scharenberg.—p. 468.
Prognosis of Cardiac Patient in Pregnancy. S. Lesse.—p. 477.
Diabetes in Pregnancy. P. M. Rike and R. M. Fawcett.—p. 484.
*Aspects in Treatment of Vulvar and Cervical Carcinoma. Grace C. Donnelly and W. A. G. Bauld.—p. 494.
*Evaluation of Adjunctive Radiotherapy in Surgical Treatment of Endometrial Carcinoma. H. Speert and T. C. Peightal.—p. 502.
Perineal Dissection for Repair. A. P. Hudgins.—p. 509.
Cesarean Section for Disproportion in Multipara. L. V. Dill, T. M. Leonard and J. B. Sheffery.—p. 515.
Gonadotrophic Hormone Therapy in Man Complicated by Antihormone Formation. J. H. Leathem and A. E. Rakoff.—p. 521.
Penicillin in Secondary Infections of Advanced Cervical Malignancies. S. Di Palma and M. Schram.—p. 534.
Meprane in Treatment of Menopausal Syndrome: Evaluation of Estrogenic Efficiency and Toxicity. D. Coulton and C. W. Sewall.—p. 541.
Rapid Obstetric Analgesia by Means of Intravenous Vinbarbital Sodium. H. F. Burkons.—p. 549.
Pregnancy in Myasthenia Gravis: Review of Literature and Report of Case. L. M. Harris and G. T. Schneider.—p. 561.
Erythroblastosis Fetalis Due to Blood Type Incompatibility. J. G. Zimring.—p. 579.
Music as Diverter in Local or Spinal Anesthesia and Analgesia. E. L. Cornell.—p. 582.

**Silver Carbonate Stain for Diagnosis of Uterine Cancer.**—Yue and his associates modified the silver carbonate staining method of Hortega for staining the cellular elements of vaginal smears. They describe the details of the procedure and stress that the affinity of chromatin material for the silver stain and the usual hyperchromatic character of atypical cells combine to make this a useful stain in the diagnosis of uterine cancer by the vaginal smear method. The cytoplasmic and nuclear characteristics of cells impregnated with silver carbonate are described, and several noteworthy advantages of the technic over other conventional differential stains are listed.

**Treatment of Vulvar and Cervical Carcinoma.**—Donnelly and her associates say that a recent survey of female pelvic cancers treated at the Radium Clinic of the Montreal Maternity Hospital from 1926 to 1945, inclusive, revealed three groups which seemed of special interest: carcinoma of the vulva, carcinoma in the cervical stump and selected cases of carcinoma of the cervix treated by radiation and surgery. There were 40 cases of carcinoma of the vulva as compared with 664 cases of carcinoma of the cervix, 177 cases of carcinoma of the uterus and 185 of carcinoma of the ovary. There were 48 cases of carcinoma in a cervical stump. Although at the Radium Clinic carcinoma of the cervix was not treated surgically, there has been a small group for whom the procedure of radiation followed by surgical treatment has been used. An effort has been made to limit this method of therapy to cases of stages I and II, though a number of stage III are included. There have been 37 of these cases. Local recurrences of carcinoma of the vulva, particularly after vulvectomy, have been few, but inguinal lymph node metastases have not been infrequent. Treatment of the inguinal lymph nodes, either surgically as recommended by Taussig, or by roentgen rays, as is now being done at the authors' clinic, would appear to be important in the initial treatment of carcinoma of the vulva. Most of the true stump cases occurred so long after subtotal hysterectomy that the diagnosis of a healthy cervix at the time of operation must have been correct. More than a third of 28 patients with true stump carcinoma were known to have had bilateral oophorectomy with the subtotal hysterectomy and, therefore, could reasonably be considered to have had no ovarian tissue at the time the carcinoma developed. This fairly large percentage does not support the theory that carcinoma of the cervix is related to ovarian stimulation. There were no stage I cases of true cervical stump carcinoma, and the majority were in stages III and IV. Though it is usual to have many patients in the more advanced stages, these figures also suggest that a patient may develop a false sense of security following operation and be more prone to disregard subsequent symptoms. The survival rate has been greatly improved with radical operation after radium treatment.

**Adjunctive Radiotherapy in Endometrial Carcinoma.**—According to Speert and Peightal total hysterectomy with removal of both tubes and ovaries is the therapeutic keystone in the management of corpus cancer. Treatment by other methods, which may be dictated by the extent of the tumor or the condition of the patient, represents a compromise. The value of adjunctive radiotherapy, in the form of preoperative application of intrauterine radium or preoperative or postoperative external roentgen irradiation, remains to be established. The authors cite reports which are representative of the recent literature on the surgical treatment of endometrial carcinoma and which fail to prove the superiority of one form of adjunctive radio therapy over another, or even to demonstrate the value of any form of supplementary irradiation over hysterectomy alone. The authors have reviewed the case records of all patients treated surgically for primary carcinoma of the endometrium on the gynecologic service of the Roosevelt Hospital from 1915 to Jan. 1, 1942. Analysis of 157 surgically treated cases of carcinoma of the endometrium has shown no benefit from preoperative irradiation with intrauterine radium. The best results in the early cases and with tumors of low histologic grade were obtained by hysterectomy alone. Postoperative roentgen therapy appeared to be of value in advanced cases and possibly for tumors of high histologic grading.

**Control of Allergy to Antirabic Vaccine.**—Slipyan points out that when Horak in 1939 reviewed reactions resulting from the vaccine therapy for the protection against rabies he revealed that an allergic reaction was present in 87.5 per cent of the paralytic cases and in 33 per cent of those cases in which neurologic symptoms did not develop. He also classified the reactions into six groups and advised gradual desensitization to the vaccine to prevent the allergic skin reaction. He reasoned that the prevention of the skin allergic reaction would prevent the neurologic sequels which can prove fatal. Horak's groups were the following: 1. Cases in which a generalized urticarial rash develops; these respond to epinephrine promptly. There is no mortality in this group. 2. Cases in which there are delayed reactions of the tuberculin type, which occur at the site of the injections. These are most common and not serious. 3. Cases in which reactions occur similar to those in group 2, but much more severe and frequently associated with fever, headache, nausea and generalized adenopathy. In this group paralysis is prone to develop, and caution should be used. 4. Cases in which there is simple neuritis involving the peripheral and cranial nerves, the facial nerve being the most commonly involved. The paralysis is usually transitory. 5. Dorsal lumber myelitis most often occurring during the second and third weeks of treatment, and characterized by the gradual onset of fever, weakness and terminating in paralysis, particularly of the lower extremities. The mortality rate is low in this group. 6. Paralysis of the Landry type—sudden in onset, often with high temperature, nausea and headache, girdle pains, retention of urine, insomnia and ascending paralysis. In one third of the cases, bulbar paralysis ensues and death occurs. Evidence pointing to an allergic causation of the vaccine reactions induced Slipyan to attempt inhibition of the skin reactions by diphenhydramine. He reports a case which fell into the third group of Horak's classification. He is convinced that diphenhydramine inhibited the skin allergy and so probably prevented more serious sequels. If this can be accomplished with such simple medication, the use of skin desensitization seems cumbersome and time-consuming.

**Tumors at Cerebellopontile Recess.**—Gonzalez Revilla says that although the diagnosis of a lesion occupying the cerebellopontile recess is relatively easy, their clinical differentiation presents a difficult problem which frequently is not solved until a microscopic examination of the pathologic specimen is undertaken. He analyzed 205 cases of tumors of the cerebellopontile recess, verified at operation at the Johns Hopkins Hospital in a period of twenty years. He gained the impression that the age of onset and duration of symptoms are the most important points in the differential diagnosis of tumors at the cerebellopontile recess. In the first two decades of life the most common tumors are the unilateral acoustic neurinomas with peripheral neurofibromatosis, the bilateral acoustic neurinomas and abscesses. The average duration of symptoms, ten years, five years and one year, respectively, helps in their differential diagnosis. Gliomas at the recess occur predominantly between 20 and 30 years of age with a duration of symptoms varying from one to three years. Between 30 and 40 years of age the unilateral acoustic neurinomas, without peripheral neurofibromatosis, and the cholesteatomas are most commonly found. The former occur in the late 30's with an average duration of symptoms of four and a half years, while the latter start to manifest themselves in the early 30's with an average duration of symptoms of seven years. The meningiomas have the same average duration of symptoms as the unilateral acoustic neurinomas, but they appear mostly between 40 and 50 years of age. After the age of 50, tumors at the cerebellopontile recess are uncommon.

**Prefrontal Lobotomy.**—Otenasek reports histories of 5 patients who were subjected to prefrontal lobotomy on account of intractable pain brought on by malignant tumors such as carcinoma of the bladder, prostate, larynx and nasal sinuses and a sarcoma of the mandible. In addition to these 5 cases there have been 6 others, of carcinoma of the kidney, the neck, breast, cervix and colon, and 1 case of a long-standing carcinoma of the nose combined with a more recent carcinoma of the prostate. One patient died of intracranial hemorrhage three days after operation; the others either are free of pain and receiving no medication or have died of their cancer. Examination of these patients after operation makes it clear that prefrontal lobotomy alters a patient's reactions to pain without materially changing his ability to feel pain. Ordinary tests of pain perception by pin prick or other methods reveal that the patient's perception of pain is unchanged. When stuck with a pin such a patient will wince, but it may be difficult to make him angry by repeatedly sticking him. Thus it is the emotional component, the reaction to pain with anxiety, discouragement and apprehension, which is counteracted by the prefrontal lobotomy. This operation relieves pain by interrupting the pathways at a psychologic rather than a physiologic level.

**Streptomycin in Influenzal Meningitis.**—Murphey discusses the therapy of influenzal meningitis with special reference to streptomycin. He reports a 21 month old Negro girl treated successfully with streptomycin in conjunction with penicillin and sulfadiazine. The various therapeutic agents should be given in amounts sufficient to guard against the development of insensitive strains. Sulfonamide drugs are given in amounts from 1½ to 3 grains per pound (0.22 to 0.44 Gm. per kilogram) of body weight per twenty-four hours. The intravenous route may be employed at first, particularly in cases in which nausea and vomiting are a problem. The change to oral medication may be made as soon as this mode of therapy becomes feasible. The sulfonamide drugs should be continued for at least two weeks after the discontinuation of the other therapeutic agents in order to insure against recurrence. Type B specific anti-influenzal rabbit serum is administered intravenously only after laboratory verification of specific sensitivity of the offending organism. Streptomycin should be given both intrathecally and parenterally, preferably intramuscularly. The intraspinal dose should not exceed 0.1 Gm. in 5 to 10 cc. of isotonic sodium chloride solution, this amount replacing a larger amount of withdrawn spinal fluid. In smaller children the initial intrathecal dose of streptomycin may be restricted to 0.025 Gm., and subsequent doses, if needed, increased to 0.05 Gm. At least one intraspinal administration is regarded as advisable since streptomycin does not diffuse into the spinal fluid to a sufficient degree to assure an antibacterial level. Penicillin may be used on occasion as a therapeutic agent directed directly against the influenzal bacillus, or as a preventive of secondary infection by streptomycin-resistant organisms. The author discusses the toxic manifestations that may result from the administration of streptomycin by the various routes. He concludes that no one therapeutic agent now available can be counted on alone to combat meningitis due to Hemophilus influenzae.

**Diagnosis and Operability of Bronchiogenic Carcinoma.**—Gibbon and his associates point out that cough, pneumonitis and pain are the earliest symptoms. Cough is also the most frequent. Sputum is a frequent but not an early symptom. Other symptoms are hemoptysis, loss of weight, dyspnea and wheeze. A positive diagnosis of bronchiogenic carcinoma prior to operation depends on microscopic examination of a piece of the tumor, which can be obtained by aspiration through a needle inserted through the chest wall into those growths which are peripherally located. This method of biopsy was not employed by the authors. It involves the danger of implantation. Bronchoscopy was done in all their cases. If the tumor cannot be seen, other suggestive evidence of neoplasm is narrowing, distortion or fixation of the trachea or bronchus. In 1946 two of the authors, Gibbon and Clerf, began to use the cytologic study of bronchoscopically removed secretions, which are aspirated through a bronchoscope from the bronchus draining the region of the suspected tumor. The material is smeared on slides and is stained by the Papanicolaou technic. When secretion cannot be obtained, 2 to 5 cc. of salt solution is introduced into the bronchus and then aspirated. The salt solution is then examined by the same technic as the bronchial secretions. One hundred and eighteen consecutive cases of carcinoma of the lung have been studied by this method. Neoplastic cells were found in approximately 90 per cent of these cases. In the same group a positive biopsy was obtained by the bronchoscope in approximately 45 per cent. Neoplastic cells were found in 43 cases in which the bronchoscopic examination was completely negative. The senior author has used these diagnostic methods in 31 patients during the past fourteen months with good results. Whenever the diagnosis is certain, an exploration should be done on all patients unless there is evidence of extension of the disease beyond the hemithorax in which the tumor lies, or unless a pleural effusion exists which is bloody or contains malignant cells. The really debatable issue, concerning whether or not exploration should be done, lies in the group with nerve palsies. Involvement of the phrenic, recurrent laryngeal or sympathetic nerves indicates an infiltrating growth which has extended beyond the confines of the lung. This does not mean that the lesion cannot be removed by block dissection including the involved nerve. When the chest is opened and all tissue involved by the growth can be removed without leaving malignant tissue behind, a radical pneumonectomy should be done. The procedure which the authors have found most effective in increasing resectability has been the intrapericardial ligation of the pulmonary vessels, as proposed by Allison.

**Treatment of Bronchiogenic Carcinoma with Methyl-Bis.**—Skinner and his associates employed methyl-bis (beta-chloroethyl) amine hydrochloride in the treatment of 25 patients with bronchiogenic carcinoma. Three patients had adenocarcinoma, 5 had squamous cell carcinoma and 17 had undifferentiated cell carcinoma. Seventeen of the 25 cases are considered in this report. Patients subjected to treatment with the drug were given a well balanced diet, which included 1 quart of milk daily and one generous serving of meat, fish or eggs with each meal. Amino acids orally are prescribed if indicated, and vitamins and ferrous sulfate are given. Smoking is prohibited. A follow-up history, physical examination, complete blood count, and either fluroscopic or roentgen examination of the chest are made every two weeks. Blood transfusions are used if indicated, as the compound is rather toxic to the bone marrow. The patient is hospitalized for five days and is given 0.1 mg. of methyl-bis (beta-chloroethyl) amine hydrochloride per kilogram of body weight intravenously once daily for four days. This course can be repeated every two or three months or more often if necessary. The drug must be used immediately after it is made up in solution. The action of the drug on the cancer cells and on the bone marrow is similar to that of roentgen rays. The authors present histories of 4 representative cases and state that they believe that the proper treatment of bronchiogenic carcinoma is pneumonectomy if at all feasible. If surgical treatment is not warranted because of extension of the carcinoma or of the presence of distant metastases, than a combination of injection of the nitrogen mustard compound and roentgen therapy offers the best aid.

**Hypertension with Papilledema Simulating Brain Tumor.**—Palmer and his co-workers direct attention to the similarity in symptoms, physical signs and spinal fluid findings between severe hypertension with papilledema and expanding intracranial lesions. They compare observations on 30 patients with severe hypertension and papilledema with those on 25 patients with expanding intracranial lesions and 15 patients with severe hypertension without papilledema. The differential diagnosis between severe hypertension with papilledema and an expanding intracranial lesion with coincident hypertension is discussed and illustrated by a report of 3 cases. The most important differential characteristic is the slow, steady progression of neurologic localizing signs in brain tumor. Proper evaluation depends on expert neurologic examination and sometimes on supplementary pneumograms. In the hands of the authors extensive sympathectomy has thus far been the measure that has relieved symptoms, reduced the papilledema and stayed the rapid progress to a fatal outcome that is almost uniform in patients with malignant hypertension. They suggest that denervation of the splanchnic bed abolishes or minimizes the orthostatic pressor responses and thus protects the cerebral circulation.

**Vitamin $B_{12}$ in Pernicious Anemia.**—Berk and his associates say that a crystalline substance, vitamin $B_{12}$, has recently been isolated from liver extracts and found to produce hematologic remissions in pernicious anemia. An unusual opportunity for testing the effectiveness of vitamin $B_{12}$ on the neurologic disturbance of pernicious anemia presented itself in a patient in whom acute combined systemic disease had developed while he was receiving inadequate doses of synthetic pteroylglutamic acid. The patient also had an acquired allergic sensitivity to injected liver extracts. It was of additional interest, therefore, to determine the relation of vitamin $B_{12}$ to this sensitivity. A hematologic remission and rapid improvement in the neurologic picture followed treatment with crystalline vitamin $B_{12}$. The patient, who had had severe local and systemic sensitivity reactions to purified liver extracts derived from both pork and beef, showed no reactions to vitamin $B_{12}$. Observations on this patient suggest that vitamin $B_{12}$, like the presently available injectable liver extracts, should prove effective against the neurologic as well as the hematologic manifestations of pernicious anemia. They also suggest that vitamin $B_{12}$ is not responsible for sensitivity reactions to liver extracts.

**Conditioned Reflex Treatment of Chronic Alcoholism.**—The conditioned reflex treatment of chronic alcoholism employed at the Shadel Sanitarium consists, according to O'Hollaren and Lemere, in the establishment of an aversion to the sight, taste, smell and thought of all types of alcoholic beverages. This is accomplished by repeated conditioning seances. From the middle of 1935 to the end of 1945 there were 3,125 admissions for the treatment of chronic alcoholism. These 3,125 cases represented persons from all walks of life. Social status ranged from the very rich to the very poor—from the highly trained professional man to the former inmates of state institutions. Practically every type of labor, trade and profession was represented, indicating that alcoholism is no respecter of person, class or intelligence. Types of personalities varied from the well adjusted man to the more severe type of psychoneurotic. From a statistical evaluation of 2,323 cases in which treatment was given, the authors conclude that 85 per cent of patients treated by this method will remain abstinent for six months or longer; 70 per cent will remain abstinent for a year; 60 per cent will remain abstinent for two years, and 25 per cent will remain abstinent up to ten years or longer. Adjuvant forms of therapy have been used more extensively since this survey has ended. Their ultimate value, however, has as yet not been fully determined. Factors such as age, occupational stability, marital unhappiness, nervousness, history of recurrent delirium tremens and financial indolence have a definite effect on the prognosis, either favorable or unfavorable. The treatment is of benefit and it is hoped that the conditioned reflex will be utilized more widely and combined with other forms of therapy in selected cases, since it assists therapists by helping the patient remain abstinent while a program of personality and environmental adjustment is carried out.

**Porokeratosis of Mibelli.**—Barker and his co-workers report 1 case of porokeratosis of Mibelli of eleven years' duration in a girl aged 15. For the succeeding twelve years her condition has been observed and treated at irregular intervals. The clinical and pathologic observations, from early adolescence through first pregnancy to the manifestation of characteristic lesions in a normal infant son of the patient, emphasized the chronic and hereditary aspects of the disease. A possible endocrine relationship is suggested by the rapid extension of the eruption during puberty and its recession during pregnancy. The four characteristic types of lesions of porokeratosis—i. e., plaquelike lesions, follicular keratoses, dome-shaped, papular and nodular hyperkeratoses and verrucous lesions—were originally presented, but the predominating plaquelike lesions were seen to develop from both the follicular and the papular lesions. This would indicate that the follicular and papular are the primary lesions and the plaquelike are the ultimate lesions. Vitamin A therapy, massive thyroid therapy, ultraviolet and roentgen treatment, as well as the local use of keratolytics, were equally unsatisfactory. Serial sections of biopsies taken from the lesions at various intervals revealed hyperkeratosis, parakeratosis and acanthosis; a striking degree of porokeratosis with apparent extension of the abnormal keratinization to the deep coil gland acini; plumelike columns of nucleated horny cells ("cornoid lamellae"); conical areas of peculiar alteration of epidermal cells in association with the emergence of coil glands; a complete or relative absence of hair follicles and sebaceous glands, and a striking degree of inflammatory reaction in the cutis with an associated tendency toward fibrosis. One may well be dealing in this case with an entity which belongs in a group with Darrier's disease and other diseases which represent possible dermatoses of a delayed nevoid origin.

**Yaws in New York City.**—Post and Sheard report 1 case of yaws in a Negro boy aged 14 whose parents were born in Martinique, French West Indies, and came to the United States six years before the birth of the patient and his twin brother. At the age of 1 year both boys were sent to Martinique to live with their paternal grandmother, and rejoined their mother in New York three months before the admission of the patient to Presbyterian Hospital. Three months before returning to the United States the patient noticed a pinhead-sized papule on the outer aspect of the left ankle. At the time the children entered the United States the lesion was still of insignificant proportions. The patient was hospitalized because the initial lesion on the leg had developed into a painful ulcer and because of general secondary eruption on favorite sites for the disease including the face, palms and soles. On the face there were numerous frambesiform lesions from 10 to 20 mm. across. The serologic reactions were positive. Dark field examinations of frambesiform lesions were positive for spirochetes morphologically indistinguishable from Treponema pallidum. The diagnosis was established on the basis of history, clinical appearance and dark field and serologic examinations. The entire background and course of the infection followed recognized descriptions of yaws. A good clinical response was obtained with a total dose of 5,600,000 units of penicillin given in fourteen days. Spirochetes disappeared from the lesion in approximately the same length of time noted by other observers. Healing of the mother yaw was delayed because of exuberant granulation tissue and active secondary infection. Martinique is one of the known endemic areas in the West Indies, but West Indies immigration data indicate that cases of frambesia will occur rarely in the United States.

**Para-Aminobenzoic Acid in Rocky Mountain Spotted Fever.**—After citing a previous report of 8 cases of spotted fever in which treatment was with para-aminobenzoic acid, Ross and his associates say that since then they have treated

9 additional cases. All of the 17 patients recovered. Both the morbidity and degree of toxicity were decreased. The earlier the initiation of para-aminobenzoic acid therapy, the better the response. Favorable therapeutic results can probably be expected if the administration of the drug is started before the seventh day. The optimal time for initiating treatment is during the first four days after the onset of the disease. There is no definite linear or curvilinear correlation between dosage and blood concentration. On the average, a dose of 0.9 Gm. per kilogram of body weight in twenty-four hours in a two hour divided dosage schedule was found to be satisfactory in children. Para-aminobenzoic acid causes few toxic manifestations.

**Neutralizing Antibodies in Families with Poliomyelitis Patients.**—Wenner and Tanner pointed out in a previous paper that whenever poliomyelitis appears in certain households all the children, and sometimes adult members, have poliomyelitis. Frequently the disease is so mild that its existence can be determined only by finding poliomyelitis virus in the stool, or, as is less readily the case, in the oropharynx. If one considers the differences in clinical response among all the members in a family in which poliomyelitis virus is widely seeded, the question arises concerning the appearance and persistence of neutralizing antibodies in these patients. In 1946 members of households were sampled to delineate the distribution of poliomyelitis virus within family units in which poliomyelitis appeared. Several members in these family units were selected for inclusion in the present study. Five of the 6 patients studied had poliomyelitis, and the sixth was a familial contact. It was found that neutralizing antibodies do appear in the serums of patients convalescent from poliomyelitis. Neutralizing antibodies, as a rule, appeared during the first ten days of illness. There is little if any fall in titer during the ensuing year. It was also evident that in some patients ill with poliomyelitis the neutralizing antibody does not reach a high level. The authors cite observations on a paralyzed patient to prove this.

**Diffuse Pancreatic Calcification.**—Reeves and Moran say that recently there have come to their attention several cases presenting diagnostic problems in which the finding of disseminated calcification by the roentgenologist served to confirm the impression of pancreatic disease. They present brief histories of 6 patients with diffuse pancreatic calcification One of the patients was a man, aged 52, and another was a child of 4. The ages of the other 4 patients were between 29 and 33 years. The chief complaint in the 5 adult patients was recurrent abdominal pain of over two years' duration. Two patients gave histories of heavy consumption of alcohol and a third had previous cholelithiasis; in the others the causation was not apparent. The epigastric pain, which is usually intermittent, may be accompanied by nausea and vomiting, loss of weight, glycosuria, steatorrhea and occasionally jaundice. Diabetes mellitus is present in about one half of the cases with diffuse calcification, depending on the extent of islet damage. Lymphatic and ascending spread of infection, stasis, and regurgitation from the biliary tract may be factors contributing to the development of pancreatic calcification. The diagnosis can be made easily with the aid of roentgenography. On a roentgenogram of the abdomen the calcium can be seen to conform to the pattern of the pancreas. Involvement may be limited to the head, tail or body. When not so diffuse, the calcification may present a problem in differential diagnosis. In such cases a lateral roentgenogram is of considerable assistance. Cholecystography or pyelography may be necessary to rule out gallstones and stones in the kidney. Surgical treatment includes removal of localized concretions, partial and complete pancreatectomy and celiac ganglionectomy for relief of pain.

**Calcification of Ascending Aorta in Syphilitic Aortitis.**—Leighton investigated the serology and clinical cardiac findings in several cases showing calcification in the ascending aorta on routine admission chest roentgenograms. These patients were found to have positive Wassermann reactions and in 1 case definite aortic insufficiency. Calcification of the ascending aorta was detected in 9 of 18 cases of syphilitic aortitis without aneurysm, proved at necropsy. There were 39 cases in which the diagnosis of syphilitic aortitis had been made at the University Hospital or the Minneapolis General Hospital. Of these, 21 showed the calcification in question. In 4 of the 21 there were aneurysms of the aorta; the remaining 17 cases, or 43 per cent of the total number, showed calcification. Of the total number 66 per cent had positive Wassermann reactions. For the purpose of control, four hundred roentgenograms of the chest were examined. These were consecutive cases drawn from a routine file. Calcification of the ascending aorta was found in 2 cases in this control group, an incidence of 0.5 per cent.

**Vinbarbital Sodium in Obstetrics.**—Vinbarbital sodium is sodium-5-ethyl-5-(1-methyl-1-butenyl) barbiturate. Lewis and Boddie review observations on 3,000 cases in which they used this substance for the induction of amnesia, analgesia and anesthesia during labor. Two thousand, four hundred and forty-four received vinbarbital sodium orally in combination with scopolamine and, in addition, vinbarbital sodium intravenously for the completion of labor. The average dose was 9 grains (0.59 Gm.) and 10 grains (0.65 Gm.) intravenously. Spontaneous delivery occurred in 1,475, or 51 per cent. Of the operative deliveries, 1,331, or 86.4 per cent, were elective outlet forceps; 144 were breech extractions; 54 were midforcep deliveries, and 7 were versions. Of the 2,978 infants born alive, 80.9 per cent breathed and cried spontaneously; 12.6 per cent were slightly asphyxiated, and required only carbon dioxide and oxygen for resuscitation; 5.4 per cent were moderately asphyxiated, and required tracheal catheterization in addition to carbon dioxide and oxygen; 0.9 per cent were greatly asphyxiated, and required tubbing in addition to the aforementioned procedures. Vinbarbital sodium appeared to have no effect on the duration of labor. After the intravenous administration of vinbarbital sodium, the uterine contractions were accelerated and dilatation progressed rapidly in the majority of cases. It was equally effective in spontaneous and operative deliveries. The "screaming" parturient who is nearing the end of her labor can be rapidly and effectively calmed with intravenous administration of vinbarbital sodium. Mild to moderate degrees of restlessness occurred in 23.4 per cent. All were promptly controlled by intravenous administration of additional vinbarbital sodium. Complete amnesia was obtained in 70 per cent of all patients who received vinbarbital orally with scopolamine. Complete amnesia was obtained in 99 per cent after intravenous administration of vinbarbital sodium. The incidence of postpartum hemorrhage was not increased. The majority of patients slept soundly for one to eighteen hours following delivery. All expressed a desire for the same method of analgesia and anesthesia for their future deliveries. The results obtained indicated that vinbarbital sodium is a most satisfactory agent for the induction of obstetric amnesia, analgesia and anesthesia.

**Surgery in Bleeding Peptic Ulcer.**—Warren and Lanman say that under current methods of conservative treatment, 1 or 2 of every 20 patients admitted with massive hemorrhage from peptic ulcer will die. These patients establish a need for surgery in the treatment of bleeding peptic ulcer. The mortality following surgical treatment seems to be directly dependent on the degree of exsanguination at the time of operation. The authors have found it useful to separate operations done during different phases of exsanguination into three categories; namely, emergency, urgent and elective. Of the 54 patients with bleeding from peptic ulcers observed by the authors, 29 had massive hemorrhage; the erythrocyte count was less than 3,000,000. In 10 of 20 who bled rapidly, the hemorrhage continued or, having stopped, it recurred. Four of these 10 were over 45 years of age and were operated on. Their postoperative courses were satisfactory and there were no deaths. One of these 4 patients operated on had a small duodenal ulcer of the anterior wall. A subtotal gastric resection with excision of the duodenal ulcer was performed. In the other 3 cases the ulcers were of the posterior penetrating variety and had eroded large arteries. Each ulcer was treated by exclusion. Since they presented three different problems in technical management which call for exclusion rather than excision, they are reported in detail. The authors stress early "urgent" operation for all patients with massive hemorrhage from peptic ulcer who are over 45 years and in whom the hemorrhage persists after forty-eight hours following admission to the hospital or, having stopped, recommences. Subtotal gastrectomy with removal of the lower two thirds of the stomach, including the pylorus, should be the surgical plan for these patients. In those patients in whom the ulcer is technically difficult to remove, a subtotal gastrectomy with exclusion, but not removal, of the ulcer is advocated. In patients with a large inflammatory mass involving pylorus and duodenum, a two stage subtotal gastrectomy as described by McKittrick should be done.

**Celiac Syndrome and Meconium Ileus.**—Hiatt and Wilson summarize all the previously reported and 15 hitherto unreported cases of association of meconium ileus with pancreatic cystic fibrosis. Eight patients among the total of 26 have been admitted to Babies Hospital in New York during the past two years. These 8 cases are described. The removal of obstructing meconium was accomplished by irrigation through an ileostomy wound and milking out of bulky masses. In 5 cases there was an association volvulus of a loop of ileum, presumed to result from excessive writhing of elongated and hypertrophied coils of small gut proximal to the obstructing inspissated meconium. In 4 of these cases the volvulus was corrected by simple unwinding. In all 8 cases associated cystic fibrosis of the pancreas existed. The authors believe that pancreatic insufficiency underlies all instances of meconium ileus. The history of pancreatic fibrosis or of meconium ileus in a sibling supports the preoperative diagnosis of meconium ileus in a newborn infant with intestinal obstruction. Of the 5 children surviving operation, only 1 has contracted chronic pulmonary disease; up to the present three children have developed normally. Since children with fibrocystic disease of the pancreas require a high vitamin intake, particularly the vitamins of the fat-soluble group, these children were given high doses of vitamins and continue to receive them. To compensate for absence of pancreatic function, pancreatin was given. The special diet, the added vitamins and the pancreatin will always be required by the children, for the pancreas is not expected to resume function and the intolerance to fats will remain. At the present time, twenty-six months after operation in the first 2 infants surviving and fifteen months postoperatively in the third survivor, these 3 children are alive and well.

**Vitamin E in Menopausal Syndrome.**—Ferguson says that although hormones are extremely helpful if used correctly they can produce undesirable reactions. In searching the literature the author found Christy's report, which discusses the possibilities of vitamin E in menopausal problems, and the work of Hain, a British writer, on the study of vitamin E in the control of flushes as contrasted to the use of estrogens. The 66 patients treated by the author were chosen because they could be relied on in giving accurate data. A preparation containing 5 mg. of alpha-tocopherol was given twice daily, after meals, by mouth for six weeks and then once daily until discontinued. In the stubborn cases vitamin E was administered also once every week by intramuscular injection until the symptoms began to abate, and then the injections were discontinued and only the oral therapy was used. Occasionally the injections had to be reinstituted. In one group of 26 patients, 22 obtained complete relief in five to eight months, while the other 4 obtained no relief from vitamin E therapy, but did get some from estrogenic therapy. In the second group of 40 patients 37 received complete relief in five to eight months, 1 after twelve months, and the other 2 received no relief from either vitamin E or estrogenic therapy. The author believes that vitamin E has demonstrated its effectiveness, although its mode of action is not understood as yet. It does not induce carcinogenic cellular action, which is sometimes thought to be aggravated by estrogenic hormones.

*Health of Plumbago Workers in Ceylon. W. L. P. Dassanayake.—p. 141.
*Diatomaceous Earth Silicosis. E. C. Vigliani and G. Mottura.—p. 148.

**Health of Plumbago Workers.**—Dassanayake says that Ceylon plumbago is considered indispensable for the manufacture of crucibles for metallurgical use. It is also used for paints, pencils and lubricants and in the electrocarbon industries. In 1945 the wages board for the plumbago trade directed the Ceylon Commissioner of Labor to inquire into the health of plumbago workers. Plumbago is found in deposits between solid granite rock. With the exception of six mines, all are worked within 100 feet of the surface. The three best managed mines are worked from 500 to 1,500 feet below the pit head. In these modern machinery and electricity are used. To prevent a dust hazard, the "wet system" is used in various work processes. Lung disease is rare among underground miners. Fifty persons who had worked for over ten years as underground miners were examined roentgenologically and roentgenograms in 4 persons showed diffuse fibrosis of the lungs. The general health of persons employed in plumbago mining is satisfactory. Sixty-two persons employed in plumbago curing sheds, where there is a greater dust hazard, were examined clinically and roentgenologically. Clinically, only 33 persons showed normal lungs. Roentgenologically, 51 persons showed abnormalities varying from fine striation to gross disease. Lung abnormalities seem to increase with increasing length of service in plumbago curing. The workers incur a considerable dust hazard in comparison with the miners in the plumbago mining industry. No protective measures are used by the plumbago curers to safeguard them from the dust hazard.

**Diatomaceous Earth Silicosis.**—According to Vigliani and Mottura, diatomaceous earth or diatomite is used for a great variety of industrial purposes, including dynamite, refractory bricks, filters and as an insulating material. Tripoli is valuable for polishing metals and precious stones. The authors have observed cases of advanced silicosis caused by inhalation of diatomite dust among workers employed in the manufacture of filter candles. Workers in two factories making filter candles (basically similar to Chamberland and Berkefeld candles) who had worked in the turning department for more than one year were given roentgen and physical examinations in 1944, and from then on once a year. Out of 20 workers roentgenologically examined in the two factories, 13 were silicotic; of these, 7 were in an advanced stage and 1 had open tuberculosis. From 1944 to date, 2 workers have died, one of silicotuberculosis and the other of silicosis; several became incapacitated and were obliged to leave work; 6 were pensioned. The most important features of the ignited diatomite dust silicosis appear to be: (1) rapid development and severe course of the silicosis; (2) a tendency to general wasting in the advanced stages of the disease; (3) tendency to spontaneous pneumothorax, owing to the presence of numerous emphysematous subpleural blebs, especially in the apex, and (4) absence of a typical nodular stage as seen in classical simple silicosis. The fibrosis set up by diatomaceous earth seems more diffuse than nodular. The reason for the difference between the mild silicosis observed among the crude diatomite workers and the malignant silicosis observed among the ignited diatomite workers lies in the fact that the ignition at 1250 C. transforms the amorphous silicon dioxide of the crude diatomite earth into microcrystalline cristobalite.

**Tubercles of Choroid.**—Illingworth and Wright report 60 patients aged less than 14, 42 with miliary tuberculosis with or without meningitis and 18 with tuberculous meningitis. Choroidal tubercles were observed in 25 (60 per cent) of the first group and in only 1 patient of the second group, in which there was no miliary spread. Of 5 adult patients with miliary tuberculosis with meningitis, choroidal tubercles were observed in 3. Choroidal tubercles are therefore of great diagnostic value in cases of miliary tuberculosis; they may establish a definite diagnosis before a roentgenogram of the chest or a lumbar puncture has been performed. In 9 cases necropsy revealed miliary tubercles which had not been detected by roentgenograms of the chest. In tuberculous meningitis miliary spread can be excluded only at necropsy. In no cases were choroidal tubercles observed merely as a terminal phenomenon. In 20 patients with choroidal tubercles well defined and definite changes were observed in these tubercles. As time passes the margin of the tubercles becomes more definite, the tubercle enlarges, the center becomes paler and the tubercle and the surrounding area become stippled with pigment. In the final stage there is a parchment-white scar with heavy surrounding pigmentation and paling of the adjacent choroid. In 8 patients in whom in spite of prolonged treatment with streptomycin the choroidal turbercles failed to progress beyond the early intermediate stage, death occurred in 5 and in the remaining 3 the response to treatment was unsatisfactory. The 3 patients in whom the tubercles progressed to the final or healed stage were apparently cured. Choroidal tubercles were observed in 4 additional cases of tuberculosis in children in which there was no meningitis or evidence of miliary spread. In 1 of these cases a solitary choroidal tubercle was seen to pass through all the stages to the final or healed stage. It seems possible that careful examination of the fundi of all patients with primary tuberculosis will, in some, reveal choroidal tubercles.

***Stainless Steel Wire for Abdominal Incisions.***—In Abel and Hunt's ten years' experience the use of stainless steel wire makes the closure of large abdominal incisions a clean procedure which is completely secure. It eliminates the risk of postoperative disruption and herniation. No such complication has occurred in over 2,500 consecutive major laparotomies, a large number of which were for malignant disease of the alimentary canal. Its use has been accompanied by a considerable reduction in the incidence of infection. Skin scars are neater. Early postoperative ambulatory treatment may be practiced with great confidence, and with the concomitant benefits of a reduced incidence of distension and of pulmonary and vascular complications. The use of stainless steel darns in the repair of hernial orifices has simplified the operation. Any hernia, however large the defect, can be repaired by this method. The closure seems to be more secure than by any other method. There was no recurrence in over 300 cases in nearly five years. The strong, smooth, fine, innocuous filament of stainless steel is the best material for the closure and reinforcement of fibromuscular planes. It must be used correctly, without tension, without strangulation of the tissues and without kinking of the wire.

Nailing the Femoral Neck by Simple Method. V. J. Kinsella.—p. 512.

**Causalgia.**—Cullen's report is based on 24 cases. He is of the opinion that the typical syndrome of causalgia develops only when the median or internal popliteal nerves are injured. He doubts whether pain associated with injury in the peripheral part of the limb, or of the brachial plexus, should be classed as causalgia. Procaine hydrochloride block of the sympathetic ganglions is important as a diagnostic method. Twenty-three injections of procaine hydrochloride were made in 17 of the author's patients. Of these, 8 were treated subsequently by sympathectomy and 9 by radiotherapy. No permanent benefit from procaine hydrochloride injection was observed. After sympathectomy, 7 patients were relieved of all pain at the end of one year; 1 complained of occasional pain in the ring finger. The improvement in these was maintained for two years after operation. Roentgen therapy alone was used in 7 patients, 3 with brachial plexus lesions and 4 with median and other peripheral nerve lesions. Two of the 3 patients with brachial plexus lesions were almost free from pain after two years and suffered pain only on excitement or exposure to cold. One showed no definite improvement and has since been treated by tractotomy. In all 4 patients with lesion of the median or peripheral nerves there was steady improvement over two years. The result was less satisfactory after roentgen therapy than after sympathectomy. While these patients were able to carry on with their work, they were still liable to mild recurrences of pain as the result of excitement, loud noises or exposure to cold. Of the remaining 9 patients, 1 was treated by alcohol injections with incomplete relief. Of 3 who were treated by neurolysis with periarterial sympathectomy in 2 and arterectomy in 1, only 1 showed slow improvement over two years which did not appear to be related to the operation. Four patients with mild causalgia received simple physical therapy including wax baths, galvanism and massage. Physical therapeutic treatment is not tolerated in cases of severe causalgia.

Renal Tumour and Persistent Fever: Report of Case. L. Zádor.—p. 256.

**Refrigerated Autogenous Skin Grafting.**—Flatt reports results of fifty applications of refrigerated grafts stored and applied to both "clean" and infected granulating areas. The fifty applications of skin were performed on 17 patients. Thirty applications were made on 10 patients for thermal, electric or roentgen ray burns; fourteen applications were made on 4 patients for failed Thiersch grafts; five applications were made in 2 patients for traumatic full thickness skin loss and one application was made in a patient with varicose ulcer. It was found that the shorter times of storage yielded a higher percentage take, but even the longer times of storage yielded a satisfactory take. The skin was usually used for grafting within the first three weeks of storage, but the occasional use of skin stored after this period proved satisfactory. The thinner the graft the more rapidly it became vascularized from beneath. The thicker split skin grafts usually separated into two layers, a lower adherent layer and an upper layer which separated with the tulle gras on which the graft was spread. The results tend to substantiate the views of other writers that refrigerated grafts possess an increased vitality. The patients have in many instances been saved repeated operations and had their hospital stay shortened by having skin available at the times at which the recipient area became suitable for grafting.

What is Silicosis? P. Heffernan.—p. 169.
*Differential Diagnosis of Tuberculous Cervical Adenitis. H. Bailey. —p. 174.

**Differential Diagnosis of Tuberculous Cervical Adenitis.**—Bailey mentions the various conditions that have been referred to him as tuberculous cervical adenitis. These included: branchial cyst, acquired branchial fistula, deep cavernous hemangioma of the neck, thyroglossal cyst, adenoma of the pyramidal lobe of the thyroid, thyroglossal fistula, dermoid cyst in Burns' space, Hodgkin's disease, carotid body tumor, enlargements of the preauricular lymph node, mixed parotid tumor, preauricular ulcer, tumors of the submaxillary salivary gland, syphilis, actinomycosis, swellings of the subclavicular fossa, staphylococcic infections and streptococcic and other pyogenic infections. There were always cases of cervical lymphadenopathy that have subsided under expectant treatment. A proportion of these, especially those in children, probably never were tuberculous. The astute clinician, when seeing a child with subacute inflammation of the cervical lymph nodes, will realize that the infection may or may not be tuberculous and will reexamine the child at weekly or fortnightly intervals. Many will perform a patch test early in the period of watchful observation, and when the test is positive it is unlikely that a doubtful mass is nontuberculous.

Nephrectomy in Hypertension and Unilateral Renal Disorder: Survey and 2 Cases; 1 Resulting in Decreasing Blood-Pressure but Persisting Tendency to Angiospastic Encephalopathy. P. Effersøe.—p. 10.

*On Treatment of Actinomycosis with Sulfonamide Drugs and Penicillin: Report of Successfully Treated Case of Pulmonary Actinomycosis. C. A. Adamson and G. Hagerman.—p. 23.

*Erythema Exudativum Multiforme: Clinical Picture. H. J. Ustvedt —p. 32.

Mediastinitis Anterior Chronica. A. J. M. Lohman.—p. 51.

Titration of Serum with Mercuric Chloride Especially in Liver Affection. T. Grinsted.—p. 66.

Vitamin Deficiencies After Prolonged Treatment with Penicillin. L. Mosonyi and Elisabeth Oblatt.—p. 82.

**Sulfonamide Drugs and Penicillin in Actinomycosis.**—Adamson and Hagerman review a small number of cases of pulmonary actinomycosis with improvement or cure following treatment with sulfonamide drugs which have been described in the literature. Of later years, some few cases of actinomycosis treated with penicillin have been recorded. The authors report a man, aged 40, who in March 1945 presented symptoms of acute pneumonia, which did not respond to treatment with sulfonamide drugs. Roentgenograms of the chest taken in March, April and May showed slight improvement of exudation and parenchymatous lesions. He was discharged from the hospital in May, but continued to complain of pain in the chest and was again hospitalized in July with a tender swelling at the right side of the chest, which failed to yield fluid on puncture. Later it increased in size and contained pus and granular debris. Actinomycosis was suspected, but could not be verified. Treatment with penicillin was begun. In November he was again hospitalized, because a sinus had developed, and now actinomyces were demonstrated in the material taken from the sinus tract. The patient was treated with penicillin, 250,000 units daily given over four months, and with 8 to 10 Gm. of a sulfonamide combination preparation and with 25 Gm. of urea per day. The effect of this treatment was dramatic. The patient was still perfectly well eighteen months after termination of treatment and failed to show indications of recurrence.

**Erythema Exudativum Multiforme: Clinical Picture.**—Ustvedt reports the first part of an extensive study on erythema exudativum multiforme. The material includes 219 cases of erythema exudativum multiforme; 80 presented at the same time lesions of the mucous membranes, and 55 showed in addition a typical erythema multiforme, and also tender nodules on the legs resembling those seen in erythema nodosum. The age distribution curve shows a maximum in the ages from 20 to 40 years. The males were in the majority up to 20 years; the females were decidedly in the majority in the other age groups. In cases in which there were lesions of the mucous membrane there were about as many females as males, whereas in the group with combined erythema multiforme and erythema nodosum 95 per cent were females. In 22 per cent one or more recurrences had taken place, more often in cases with lesions of the mucous membranes (40 per cent), than in the combined group (2 per cent). Prodromal symptoms, chiefly pains in the joints, on the contrary were more frequently found in the latter group. In 3 cases the clinical picture of primary, atypical pneumonia was observed. The stomatitis corresponds to what is seen in aphthous stomatitis. In cases in which there were lesions of the mucous membranes the eye defects always corresponded to catarrhal, bullous or purulent conjunctivitis, whereas in the group with combined erythema multiforme and erythema nodosum episcleritis was found in the half of the cases with ocular lesions. Transitory proteinuria was noted in 16 cases; acute hemorrhagic nephritis in 1. In 7 cases symptoms of the nervous system appeared, with 1 case of polyradiculoneuritis and 1 case of choriomeningitis. One case had a fatal issue. The sedimentation rate showed in 23 of 179 cases values above 100 mm. after one hour. High figures were especially characteristic of the cases with combined erythema nodosum and erythema multiforme.

Cushing's Syndrome Caused by Primary Carcinoma of Adrenal Cortex. H. Pickert.—p. 289.

**Fatal Hypoglycemia in Diabetes Resulting from Malnutrition.**—Wendt and Arnold report 1 case and review observations on 4 other cases of diabetes in which there was exposure to shortage of insulin and to severe malnutrition. The patient whose case is reported died of hypoglycemic coma and necropsy revealed atrophy of the pancreas with cirrhosis and extensive atrophy of the island apparatus, bronchopneumonia in both lower lobes and complete disappearance of fat tissue from the adrenal cortex. All of the patients had severe diabetes and were treated with insulin for years. The general condition, particularly the state of nutrition, was extremely poor; weight deficiency was as much as 21.6 Kg. (48 pounds); some presented severe hunger edema. All had severe attacks of hypoglycemia. Although the infusion of dextrose increased the blood sugar, it did not counteract the coma. All of these cases were observed during the period when starvation was greatest. The authors point out that the hypoglycemia attacks observed in these severely undernourished diabetic patients resemble the conditions which Houssay and his associates observed in dogs with pancreatic diabetes in which the hypophysis had been removed. The hypoglycemia attacks are caused by disturbances in the diencephalohypophysial system, which in turn are the result of inanition. The adrenals also seem to be involved.

**Desoxycorticosterone Acetate in Adrenal Insufficiency.**—Heni in reviewing the present status of treatment of adrenal insufficiency points out that the different substances that have been isolated from the adrenal cortex can be classed into three groups: 1. Desoxycorticosterone and its acetate influence chiefly the electrolyte and water exchanges. 2. The so-called corticosterones influence chiefly the carbohydrate metabolism, and the 17-hydroxycorticosterone exerts an effect on the elimination of sodium chloride. The author is concerned with therapeutic application of desoxycorticosterone, the only substance available to him for treatment of adrenal insufficiency. He reviews observations on 21 patients and cites experiences of other observers. The dosage, the intramuscular injection, the perlingual administration and particularly the subcutaneous implantation of tablets are evaluated. The author used the latter method on 8 patients and found that the effect of the implantation of 100 mg. tablets persisted for seven to twelve months, averaging about eight months. The progressing adrenal insufficiency gradually involves other incretory organs by way of the hypophysis. Thus treatment of adrenal insufficiency should not be limited to substitutional adrenal cortex therapy. It is advisable to supplement it by administration of extracts of the anterior hypophysis and at least temporarily by estrogenic or androgenic substances.

Short Report on Possibility of Control of Artificial Hypoprothrombinemia with Glycocoll-Ascorbic Acid-Calcium Preparation ("Finestal"). T. Halse.—p. 425.

**Hypernephroma, Hypertension and Renal Function.**—Bohn reports 57 patients between the ages of 42 and 82 with hypernephroma, 23 of whom presented hypertension. In 8 patients the hypertension was of the renal type, while 15 presented the picture of essential hypertension. In both groups those with and those without hypertension, the majority of patients were between the ages of 55 and 65 years. No causal relationship could be demonstrated between nephroma and hypertension, and that applies to essential as well as to renal hypertension. Renal hypertension did not occur in patients with extensive unilateral or bilateral tumors in the kidneys. Hypertension did not occur even in the 3 patients with additional bilateral occlusion of the veins of the kidney by tumor tissue. Six patients presented the so-called "extrarenal kidney syndrome"; extensive metastasis to the liver was observed in all of them. A close biochemic relationship between the albumin of the liver and of the kidneys may be considered responsible for the occurrence of immunobiologic reactions, which are directed simultaneously against liver and kidneys resulting in a "serous inflammation" of the vascular apparatus of these organs. The adrenals likewise may play a part in these vascular lesions, which may involve large areas of the terminal blood vessels. An isolated disturbance of secretion of urine was demonstrated in 8 patients by Volhard's test. The largest half-hour amount was between 100 and 150 cc.; the four hour amount was around 600 cc. After the surgical removal of the tumor the test revealed normal conditions. Sixteen patients presented between 5 and 12 per cent eosinophils; 3 patients had mucous or muco-ulcerous colic; 2 patients had a so-called acute tumorous endocarditis; 1 patient aged 60 had acute polyarthritis for the first time, and 1 patient aged 67 had acute diffuse glomerulonephritis. These various immunobiologic syndromes may result from the absorption of albumin from the tumor tissue and from the tissues of the organs affected by pressure damage.

*Late Results of Unilateral Splanchnicectomy in Treatment of States of Hypotonia of Biliary Ducts. P. Mallet-Guy and M. Jaubert de Beaujeu.—p. 157.

**Splanchnicectomy for Biliary Hypotonia.**—Mallet-Guy and Jaubert de Beaujeu performed splanchnicectomy on 92 patients, 75 women and 17 men between the ages of 16 and 74, 33 of whom had gallbladder atony, 21 essential diffuse hypotonia of the bile ducts, 16 hypotonia of the common bile duct and 22 hypotonia of the common bile duct associated with chronic pancreatitis. Diagnosis of gallbladder atony was established by clinical observation and cholecystography, or by manometric and roentgen ray control during operation. Hypotonia of the common bile duct as a functional disturbance was demonstrated by cholangiography and by manometric recordings during operation. Hypotonia of the common bile duct may be an isolated disturbance or may be associated with hypotonia of the gallbladder, with cholelithiasis or with disease of the cystic ducts or even with the existence of calculi in the choledochus. Hypotonia of the common bile duct was observed during repeated operation in patients with recurrence of symptoms after cholecystectomy. This hypotonia appeared to be the only causative factor in postoperative pain and cholangitis. Hypotonia of the biliary ducts is frequently associated with chronic pancreatitis; this association presents the main indication for splanchnicectomy. Follow-up for one to six years was carried out in 88 of the authors' cases. Results were satisfactory in 81. There were 7 failures and 1 postoperative death. The fatal case was due to the additional resection of the external horn of the semilunar ganglion, which affected the vagal conduction and induced secondary paralysis of the stomach and duodenum.

*Late Postoperative Pulmonary Atelectasis. Syndrome of Late Spastic Atelectasis of Left Inferior Lobe in Association with Acute Segmented Dilatation of Colon. M. R. Castex and E. S. Mazzei.—p. 1577.

**Late Postoperative Pulmonary Atelectasis.**—The clinical form of pulmonary atelectasis described by the authors has not been previously reported in the literature. The subjects of this report, a woman and a man, were subjected to a cholecystectomy for biliary lithiasis. Gas anesthesia was used. The postoperative stage was uneventful, up to the ninth and the fifteenth day, respectively, after the operation, when clinical symptoms of acute segmental dilatation of the colon appeared in association with clinical and roentgen symptoms of atelectasis of the inferior lobe of the left lung. Treatment consisted of orthosympathetic depressor drugs and cathartics. The authors believe that this form of atelectasis is due to bronchial spasm of segmental colonic orthosympathetic reflex origin which disappears when the colonic disorder and the consequent bronchial spasm subside.

Schwannoma of Pancreas, L. Cornil, R. de Vernejoul, H. Gastaut and R. Muratore.—p. 605.
*Frequency of Ovarian Metastasis from Cancer of Breast. A. Sicard.—p. 606.
Results of Vaccination Against Diphtheria in Spain. R. Rendu.—p. 606.

**Ovarian Metastasis From Cancer of Breast.**—Sicard reports 38 cases of cancer of the breast, in women between the ages of 35 and 72, 11 of whom had ovarian metastases. Castration was performed on 23 of the 38 patients after amputation of the breast. None of them presented any signs of metastasis, but in 2 metastasis was present in the ovaries, which appeared entirely normal. The remaining 15 patients presented early or late metastases of bones, lymph nodes or viscera after amputation of the breast or in the absence of any local treatment of the tumor. Nine of them presented metastases of the ovaries. In 3 the metastasis was demonstrated on surgical intervention, but in 6 only on microscopic examination of the specimen. In 2 patients castration had been performed by irradiation resulting in menopause, but the atrophied ovaries presented cancerous cells. The high incidence of metastases of the ovaries from cancer of the breast suggests advisability of surgical castration rather than of castration by irradiation, and preferably a hysterectomy which, besides its hormonal role, may suppress a latent cancerous localization in a large number of cases.

*Cardiopathy in Chagas's Disease in Central Zone of Chile: Preliminary Report. T. Pizzi, J. Valls and R. Florenzano.—p. 315.
*Venous Thrombosis: Review of 161 Cases. L. Figueroa G.—p. 341.

**Cardiopathy in Chagas's Disease.**—Pizzi and collaborators carried out clinical and electrocardiographic observations on 411 Chilean patients with chronic trypanosomiasis cruzi in the central rural zone of Chile and in 66 normal persons of the same zone. They found that the general health of the patients was good. Cardiac insufficiency was rare. When it appeared it was mild and was caused by factors other than Chagas's disease. The capacity for work was normal. Electrocardiographic changes consisted mainly of an auriculoventricular block and right bundle branch block, of Wilson's type, they were present in 43 of 397 electrocardiograms. Clinical studies and laboratory tests failed to show pathogenetic factors other than trypanosoma as cause of the alterations. Rural, chronic trypanosomiasis in Chile is benign, and of slow evolution. It causes mild myocardial lesions in a small percentage of the patients.

**Venous Thrombosis.**—Figueroa G. analyzed the records of 161 patients with thrombophlebitis or phlebothrombosis who were observed in the last six years in the principal hospitals of Santiago. Surgical trauma, delivery and abortion were the most frequent causal factors. Thrombosis was unilateral in 111 cases, in 86 of which only the left leg was involved. Pulmonary embolism was a complication in 9 of 13 cases with phlebothrombosis and in 14 of 148 cases with thrombophlebitis. The embolus was solitary in 13 of the 14 cases complicating thrombophlebitis and multiple in 1 case of thrombophlebitis and in 9 cases of phlebothrombosis. In all cases of embolism the accident occurred during the first two weeks after the appearance of venous thrombosis. In more than half the cases the embolus was located at the base of the left lung. Anesthesia of the lumbar sympathetic is the best treatment for thrombophlebitis, whereas anticoagulants and vein ligature is the treatment of choice for phlebothrombosis.

# Book Notices

**Hemostatic Agents with Particular Reference to Thrombin, Fibrinogen and Absorbable Cellulose.** By Walter H. Seegers, M.S., Ph. D., Professor of Physiology, Wayne University College of Medicine, Detroit, and Elwood A. Sharp, M.D., Sc.D., Director, Department of Clinical Investigation, Parke, Davis and Company, Detroit. Fabrikoid. Price, $4.75. Pp. 131, with 27 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2, 1948.

The technic of hemostasis has been revolutionized, within less than a decade, by the development of concentrated stable thrombin preparations and of absorbable materials such as oxidized cotton, fibrin foam and gelatin foam. Many aspects of the subject are compactly reviewed in this small book.

The opening chapter gives an interesting survey of the chemical reactions involved in the process of blood clotting. This highly controversial topic is given as unified a treatment as possible from the point of view of Dr. Seegers, whose contributions in this field in recent years have been second to none. The bibliography covers the literature only through the year 1946. Therefore, some major advances occurring in 1947 are necessarily unmentioned: for instance, the work of Seegers himself, and others, on the plasma accelerator factor (Ac-globulin), and the work of Ferry and Morrison and of Hawn and Porter on the structure of the fibrin clot. It is regettable that, presumably through delay in publication, the gap between the information in this chapter and the present state of our knowledge should be as large as it is.

Chapters II, III and IV cover the process of topical hemostasis with thrombin alone, the chemical properties of fibrinogen and its clinical use. Chapter V treats at length of oxidized cellulose, and chapter VI gives a brief discussion of fibrin foam and gelatin sponge. The discussion of thrombin deals almost entirely with thrombin from bovine blood, although the extensive use of human thrombin, from blood collected by the Red Cross during the war, is briefly mentioned. The chapter on fibrinogen treats topics not directly related to the problem of hemostasis, such as skin grafting and the use of fibrinogen and thrombin in the pyelolithotomy operation. Nerve suture by fibrin fixation is briefly discussed.

The book can be recommended as a useful presentation of modern technics in hemostasis and of their background in the chemistry of blood clotting.

**Total Protein, Globulin and Albumin in Lumbar Fluid in Cryptogenic Epilepsy: A Clinical Methodological Study.** By Richard Eeg-Olofsson. Acta psychiatrica et neurologica Supplementum 50. Paper. Pp. 192, with 6 illustrations. Stockholm, 1948.

The author has measured the total protein and the globulin-albumin quotients in 133 patients with epilepsy (21 of these "symptomatic") and in 67 "control" patients. The data are presented in detail in fifteen tables and four charts, and discussed intelligently against a background of more than 200 references. The method of Izikowitz was employed. In 5.5 per cent of 110 patients with cryptogenic epilepsy, the total protein was above the normal limit. The globulin-albumin quotient was below normal in 10 per cent. This abnormal ratio was due both to unusually low values for globulin and high values for albumin. Measurements on successive occasions might produce different values. Thus, a subnormal quotient was found at least once in 17 per cent of 110 patients. However, abnormalities could not be related to the time interval after a seizure, to the frequency of attacks, to the duration of the epilepsy or to electroencephalographic foci. Although some of the case histories give evidence of the presence of pathologic changes in the brain, the author seems to suggest an etiologic role for the protein by proposing the term "epilepsia hyperproteinorrhachia." The low globulin-albumin ratios are not due to low values of total protein, nor are they confined to cryptogenic cases. They may be related to alterations in the permeability of the blood–spinal fluid barrier.

This is a painstaking though somewhat disconnected presentation of a mass of clinical and laboratory data. The author has difficulty in deciding whether certain cases should be classed as symptomatic or cryptogenic. Apparently he does not consider that a given case may be the result of both genetic and acquired factors.

**Everyday Miracle: Through Intimate and Sympathetic Observation of Animals, a Brilliant Scientist Illuminates the Miracle of All Life.** By Gustav Eckstein. Cloth. Price, $2.75. Pp. 235. Harper & Brothers, 49 E. 33d St., New York 16, 1948.

If there is another book which even remotely approaches the character of this one, this reviewer has not seen it. It is a presentation of observations which appear haphazard and disconnected and yet fall into a pattern. There are twenty chapters, each with a theme, such as time, hunger, life, exercise, hearing, fight, sleep, posture, sex and death. For each chapter the author presents observations on animals, such as a cat that knows Monday, storks that talk Egyptian, the smell of twelve million headless codfish and their severed heads, a rabbit which adopted a family and a spotty dog that walks on two feet. The presentation of careful scientific observations is given life and interest by the author's vivid imagination, his whimsical fantasy, and an occasional touch of mordant humor, such as the opening sentence of one chapter: "I was told this by a pretty woman, but I believe it."

This book should take its place among the classics of interpretive medical writing for lay consumption. It is comparable to Cannon's "Wisdom of the Body" and Sherman's "Science of Nutrition." It is the kind of book that a doctor can pick up for relaxation. At the same time, he will learn much about animals which he has never had occasion to know before. Not least among the charms of this book is its style, which is always fresh and original, sometimes jerky and teeming with surprise twists which keep the reader's interest constantly alert.

**Medullary Nailing of Küntscher.** By Lorenz Böhler, M.D., Director of the Hospital for Accidents in Vienna. First English edition revised by the Author. Translated from the Eleventh German edition by Hans Tretter, M.D., Surgeon in Charge of the New Jersey Manufacturers Hospital, Trenton, N. J. Cloth. Price, $7. Pp. 386, with 1261 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This book, originally published in German as the third volume of Böhler's work on fractures, is most welcome. Medullary nailing has not been extensively used in this country, nor has there been much of a tendency to add it to our armamentarium. Böhler presents the subject objectively and in a comprehensive manner. The treatise is based on a study of hundreds of cases and many thousands of roentgenograms. He states clearly that the method has a narrow field of application. In his own words, "It is evident that closed medullary nailing is suited chiefly for transverse fractures of the femur in the middle third and for localized osteitis fibrosa cystica, whereas in other fractures it frequently entails more disadvantages than advantages." He emphatically is opposed to its use by open operation and presents conclusive evidence to disclaim the original contention of Küntscher that the nail is a stimulus to formation of callus.

In spite of the rather narrow field which Bohler claims for the Küntscher nail he presents a complete system of treatment for every long bone with copious illustrative roentgenograms and apparatus and careful outlines of methods. Much of this he condemns after a thorough exposition. In a sense this book is more of a treatise than a text, dealing as it does with a method of treatment not widely accepted and limited by the author of the book to relatively few situations.

As an addition to the literature of fracture surgery, the book is "must" reading for those who use or intend to use this method as part of their armamentarium. It goes a long way toward defining the field of usefulness of this new method and will help a great deal in preventing too wide a swing of the pendulum, as usually occurs with any new method. Dr. Böhler is to be congratulated on a fine presentation and Dr. Hans Tretter for his excellent translation.

**A Handbook of Charting for Student Nurses.** By Alice L. Price, R.N., B.S., Director of Nurses, Alton Memorial Hospital, Alton, Ill. Third edition. Loose-Leaf. Paper. Price, $3.75. Pp. 386, with illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

This book is a carefully prepared guide for student nurses, giving detailed information on methods of hospital charting. It gives instruction on lettering and illustrates charting procedure in relation to each of the forms that are commonly employed in a complete clinical record. Practice pages are likewise included and more can readily be added, since the material is conveniently arranged in looseleaf form. The book also contains general rules for charting, a list of standard abbreviations and symbols, a table of foods and diet classification, and a comprehensive list of terms commonly used in charting. In schools of nursing education the handbook will serve as a valuable teaching aid.

**Cirrosis de higado, estadios previos: Histofisiologia normal y patológica del higado, pruebas funcionales y tratamiento.** Por le Dr. Luis Bernardo Rabinovich. Prólogo por el Dr. Andrés López Garcia. Premio "Facultad de ciencias médicas." Paper. Price, 40 pesos. Pp. 707, with illustrations. Editorial Cayetano Vergara, Loria 60, Buenos Aires, 1948.

This monograph on cirrhosis of the liver is based, in addition to an exhaustive review of the literature, on observations on 41 patients treated conservatively and on the study of twenty-seven biopsies obtained in course of operations performed for various lesions of the biliary tract.

The author begins in a systematic manner with the embryology, anatomy, histology and physiology of the liver and proceeds to describe the pathologic changes characteristic for cirrhosis, its various stages, pathogenesis, experimental findings, interrelations with the spleen and prodromal symptoms. Case histories are followed by a description of clinical and laboratory findings, hepatic function tests in general and those considered characteristic for cirrhosis, such as Takata-Ara, Weltmann and Hanger reactions. The last part of the book deals with complications of cirrhosis, its classification and medical and surgical treatment.

The author differentiates two stages of cirrhosis, (1) the stage of evolution and (2) the so-called cicatricial cirrhosis which represents the final, irreversible phase of the condition. All hepatic function tests are of little practical value in the recognition of early stages of the lesion or so-called precirrhosis, which, however, can be detected in biopsies. Therefore the author makes a strong plea for this procedure in contradistinction to a liver puncture, which is considered hazardous. A specimen for biopsy can be obtained in course of other surgical interventions or by means of a special laparoscopy. Only in this manner can precirrhosis be detected and the responsible factors possibly eliminated.

Of 707 pages, the case reports occupy not less than 218. The question suggests itself whether a tabulation of the results and a brief synopsis would not serve the same purpose.

Recent advances in the surgical treatment of cirrhosis, such as the portocaval shunt or its modifications, are not mentioned by the author.

The book is illustrated with black and white photomicrographs and diagrams. The index is inadequate. The book is well written, well designed and fills its purpose well.

**Let's Tell the Truth About Sex.** By Howard Whitman. Cloth. Price, $2.50. Pp. 242. Pellegrini & Cudahy, Inc., 65 5th Ave., New York 3; George J. McLeod, Ltd., Toronto, Canadá, 1948.

The title establishes the theme of this book. It is a fine, straightforward piece of work, starting in the first chapter with emphasis on what everyone knows but few acknowledge, that there is nothing wrong with sex but there is a great deal wrong with the attitude of human beings toward this vital function. Just how necessary it is to establish the concept that sex is respectable is indicated by the necessity for devoting three chapters to a justification of early sex teaching and two more to the words and sentences to be used in such teaching. After these five preliminary chapters the author devotes chapters 6 and 7 to presenting material suitable for little children and for those somewhat older. Then through three chapters he deals with special problems, such as nudity, masturbation, venereal diseases, crushes, necking and petting and "the need for sex." Marriage counseling, sex in the schools, moral issues and a final chapter entitled, "Save Sex—and Maybe Civilization, Too" complete a well rounded discussion. Particularly useful is the clarification of the so-called "Catholic opposition," which the author fairly points out is not opposition to sex instruction as such, but insistence that it be done in the home and in the church rather than in the school.

Among the many books on this subject of sex, this one can be recommended with assurance.

**The Machinery of the Body.** By Anton J. Carlson and Victor Johson. Third edition. Cloth. Price, $4.50. Pp. 639, with 220 illustrations. University of Chicago Press, 5750 Ellis Ave., Chicago 37, 1948.

This reviewer has often decried the tendency to write new textbooks which do not present a new approach to subject matter. Those remarks do not apply to this work. Although the first edition appeared twelve years ago, this edition is again a refreshing and stimulating presentation of material old to the professional physiologist, but as invigorating as if totally new. The worst criticism is the unevenness of the level of appeal. For the most part the presentation is aimed at the level of the intelligent college student. At times, however, the textual material seems most suitable for the level of the advanced seminar in physiology, except for its brevity. Perhaps this is inevitable and is not too serious. Sections in which important revisions have been made in response to new developments are blood, body defenses, emotions, cancer, and radioactive substances. The extent of treatment is necessarily brief for each subject heading, but the approach is sound and conclusions conservative. Illustrations are largely new, original and aptly applied.

**Klinische Hämatologie.** Von Dr. Hanns Fleischhacker. Cloth. Price, $19. Pp. 624, with 277 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Wilhelm Maudrich, Spitalgasse 1B, Wien IX/2, 1948.

This is a well written textbook of hematology representing the view of the Vienna school of hematologists, corresponding to the American hematology of about fifteen to twenty years ago. The newer discoveries are however, discussed, including use of liver extract in pernicious anemia, the Rh factor, and the use of folic acid, but the literature does not reach to the use of radioactive phosphorus in polycythemia, or the more modern methods of hemoglobin determination. There is little reference to American literature after 1940, but European references after that date to 1947 are given. Unfortunately, a defect in the printing of the colored pictures makes most of them entirely useless, but some of the black and white pictures are excellent. The book contains some valuable data from the extensive material available to the author, but does not replace some of the more extensive American or British works.

**The Truth About the Stork.** By Edward F. Griffith, M.R.C.S., L.R.C.P. Cloth. Price, 6s. Pp. 136, with 59 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1, 1948.

This is another crusade against the poor old stork, emanating this time from the British Empire. The book was published in London. It is a gesture toward frankness, but the photographs of the male and female nude are from the rear. All the other illustrations are diagrams, with the exception of a few innocuous photographic fillers. Factually the book is satisfactory. The presentation is without originality and most of the drawings are relatively crude. Despite all that one hears about the shortage of paper, this book is wastefully printed. Several whole pages are devoted to illustrative drawings which contribute little or nothing, and there is considerable waste space on pages where single paragraphs or small groups of paragraphs occupy half a page and the remainder is white paper. The white space is not even utilized to give the book attractiveness.

This may be classified as a useful but not particularly attractive publication.

**Dental Education Today..** By Harlan Hoyt Horner, Secretary of the Council on Dental Education of the American Dental Association, Chicago. Cloth. Price, $6. Pp. 420. University of Chicago Press, 58th St. & Ellis Ave.; Chicago 37; Cambridge University Press, Bentley House, 200 Euston Rd., London N.W.1, 1947.

This book, which describes the present status of dental education in the United States, is based on the survey of dental schools conducted in 1942-1943 by the Council on Dental Education of the American Dental Association. First, however, it presents a historical review of the establishment and development of dental schools as well as the early attempts at standardization in this field. Prior to 1840, when the first dental school was established in the United States, the method of training was mainly preceptorial in type. In the period 1840 to 1884, twenty-nine dental schools were organized, all but eight of which have survived to the present time either under the original control or through mergers or amalgamation with other institutions. By 1895, there were forty-four dental schools in existence, while the peak of fifty-seven was reached in 1900. Twenty years later the number of schools had been reduced to forty-six, and at present forty dental schools are in operation, practically all under university control.

Since 1840, approximately one hundred and twenty-five efforts have been made to establish individual schools. The commercial schools multiplied most rapidly at the turn of the century, but as standardization progressed it soon became evident that professional education cannot be maintained at a satisfactory level if geared to a profit motive. In the dental field the last proprietary school ceased to exist in 1929.

Efforts to improve dental education were in evidence as early as 1866 through the formation of special societies and associations, many of which have survived to the present day. Actual standardization in this field did not begin until 1909, however, when the Dental Educational Council of America was formed. This agency, composed of representatives of the National Association of Dental Examiners, the National Association of Dental Faculties and the National Dental Association (now the American Dental Association), issued standards for dental schools in 1916. The first classification of dental schools was made in 1918 when thirteen were designated as class A, twenty-six as B, seven as C, and two not classified. Annual lists of approved schools were issued thereafter until 1934, when thirty-five schools had attained an A rating and three the B classification, the C listing having been discontinued in 1926.

The book contains ten chapters which describe the present organization of dental schools, physical plants, geographic distribution, brief sketches of individual schools, financial management and support, faculties, students, curriculum and methods of teaching. Auxiliary areas are also included such as graduate and postgraduate education, courses for the training of dental hygienists and dental technicians, the requirements for the approval of dental internships and residencies, the training and recognition of specialists in dental practice and dental licensing examinations. While this comprehensive report concerns primarily the field of dentistry, it will also be of great interest to schools of medicine and individual physicians, since in many respects medical education and dental education represent parallel disciplines.

**The Hospital Purchasing File.** Established 1919 as the Hospital Yearbook by the Modern Hospital Publishing Co., Inc. Twenty-Fifth edition, 1947-1948. Boards. Various pagination with illustrations. Purchasing Files, Inc., 919 N. Michigan Ave., Chicago 11, 1947.

The Hospital Purchasing File, now in its twenty-fifth edition, is an excellent reference on hospital buying. It contains an alphabetical list of manufacturers and distributors, a directory of hospital products of more than 200 pages, and a group of twenty-one manufacturers' catalogs classified on a departmental or service basis. These groups include administrative, dietary and housekeeping services, laundry, building construction and maintenance, plant operating equipment, professional services and facilities pertaining to surgery, radiology, pathology, obstetrics, anesthesia, pharmacy and other departments. A further reference section contains equipment and supply lists for hospitals of fifty, one hundred and two hundred beds and other valuable information in the planning of hospital departments and services. The book is an excellent source of information and reference for those who are concerned with the services of supply, hospital operation and maintenance.

**Cancer: Hérédite, Hormones, Substances Cancérigènes. Tome I.** Par le Docteur J. Maisin, professeur à l'Université de Louvain, Louvain. Paper. Price, 84 francs. Pp. 248. Casterman, S. A., Tournai, Belgium; Paris, 1948.

This work is divided into essentially three portions: (1) the relationship of heredity and cancer, (2) the role of hormones in cancer and (3) a discussion of carcinogenesis. Each of these subjects is discussed in its relationship to the general problem of cancer. The chapter on carcinogenesis is particularly well written and complete. A pertinent bibliography is included. The book is well written and should be of value to the physician who is desirous of acquiring information about the heredity and endocrinology of cancer and a knowledge of carcinogenesis.

**Minor Surgery.** By R. J. McNeill Love, M.S., F.R.C.S., Surgeon, Royal Northern, Mildmay Mission and Metropolitan Hospitals, London. Third edition. Cloth. Price, 22s. 6d. Pp. 430, with 221 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C.1, 1948.

"Minor Surgery" is a well illustrated small manual on the essentials and elementary principles of surgery. It is divided into thirteen chapters, which include discussions on examination of the patient, antisepsis and asepsis, cellulitis, hernia and minor surgical operations.

The book is written in clear simple language. Facts are accurate and convey present day teaching and opinion. Illustrations, excellent pen and ink sketches and retouched photographs, enhance the text.

The book fulfils the purpose of a guide for hospital residents and general practitioners who encounter surgical conditions only occasionally.

**l'exploration de la fonction respiratoire: Physiologie, méthode d'exploration, indications et résultats.** Par Jaques Arnaud, médécinchef du Sanatorium du Mont-Blanc, Pierre Tulou et Robert Mérigot, médecins assistants au Sanatorium du Mont-Blanc. Préface de E. Rist. Paper. Price, 425 francs. Pp. 317, with 54 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris $6^{e}$, 1947.

After a résumé of the physiology of respiration, the authors describe the methods available for the clinical study of general respiratory function, together with the results obtained in a variety of clinical conditions. The technic of "bronchospirometry" for studying the function of each lung separately is given in considerable detail with illustrative case histories, diagrams and tables, to define the indications and limitations of the several procedures. Specific technics are described more fully in an appendix. This volume will be most helpful to those interested in newer methods of studying respiratory function in the clinic.

**Hemolysis and Related Phenomena.** By Eric Ponder. Cloth. Price, $10. Pp. 398, with 69 illustrations. Grune & Stratton, 381 Fourth Ave., New York 16, 1948.

Students interested in hemolytic phenomena will welcome this scholarly and up to date presentation. The previous monograph by Ponder on the "Mammalian Red Cell and Properties of Hemolytic Systems" was written in 1934. The present monograph is a critical presentation reflecting not only the author's large fund of authoritative knowledge in this field but his mature thinking on some of the more controversial aspects of the subject. The monograph is not strictly a source book on the subject (although it serves this function equally well), but a critical analysis and discussion of the biophysical and biochemical aspects of the mammalian red cells and hemolytic phenomena written in a most engaging and provocative manner. Although a large body of information is concisely reviewed it is comprehensive in scope and should satisfy the most exacting needs of students in this field. The broad content of the monograph is concerned with shape changes in the erythrocyte unaccompanied and accompanied by volume changes, cytochemistry and architecture, kinetics, inhibition and acceleration of hemolysis and hemolysis in vivo. The monograph is well supplied with tables, diagrams and a critically selected current bibliography. Every student of hematology will want this outstanding contribution in his personal library.

**Indice bibliográfico da lepra 1500—1945. Volume III: Q—Z.** Organizado por Luiza Keffer, bibliotecária do Departmento de profilaxia da lepra de São Paulo. Paper. Pp. 1435-1936. Biblioteca do Departmento de profilaxia da lepra do estado de São Paulo, Caixa postal 27-B, São Paulo, 1948.

Volume III of the "Indice Bibliografico de Lepra" includes entries covering Q-Z and is the final volume of this excellent bibliography on leprosy compiled by Luiza Keffer, Librarian of the Department for the Prevention of Leprosy of the State of São Paulo. Reviews of volume I (A-H) and Volume II (I-P) will be found in THE JOURNAL, Sept. 15, 1945 and Aug. 7, 1948.

**How Life Is Handed On.** By Cyril Bibby, M.A., M.Sc., F.L.S. Cloth. Price, $2. Pp. 159, with illustrations. Emerson Books, Inc., 251 W. 19th St., New York 11, 1947.

This is a wonderful book for adolescents, to explain reproductive systems of man and beast. The style of writing is easy and direct. Illustrations are informative and ample. The book explains things as most parents wish they could, and leaves little to the child's imagination.

# Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

## ASTHMA AND CORONARY OCCLUSION

*To the Editor:*—A man, 41 years of age, has had bronchial asthma for twenty years, due in part, it seems, to chronic sinusitis. Although present the year round, it is severest from August 15 to May 15. Relief is obtained mainly by epinephrine in oil, although occasionally aminophylline is sufficient. In addition, he has a multiple allergy, the most predominant being to ragweed pollen. Acute coronary occlusion developed on July 19, with myocardial infarction but the patient is showing good recovery. Is it advisable to continue the use of the epinephrine in oil for the relief of the asthma?

M.D., Canada.

ANSWER.—The history given suggests that this patient is sensitive not only to ragweeds but to many other substances. One should suspect in this sort of case air-borne molds and household environmental substances, such as feathers, cottonseed, house dust and animal emanations. Sinusitis as a cause of asthma is usually not of primary importance in such cases. It is important that you make an accurate and complete diagnosis of the causes of this patient's condition in order to treat asthma of such long duration, i. e., eight months out of the year. This diagnosis should depend on more than cutaneous tests. The following suggestions are made for treatment during an acute episode:

1. Preparation of the patient's bedroom to remove all allergens to which the patient may be sensitive. There are patients who are sensitive to feathers only during the ragweed hay fever season or during the period when they are exposed to large amounts of other air-borne allergens. It is not unusual for patients to tolerate a certain amount of feather dust at other times of the year with little or no symptoms. Feather pillows and mattresses should therefore be covered by well made allergen-proof covers or rubber pillows and a rubber mattress, if available, should be used. House dust precautions should be carefully carried out, i. e., the removal of rugs from the floor, the avoidance of drapes and hangings in the bedroom and the use of chairs which are not upholstered. Perfumes and flowers should not be allowed in the room.

2. The use of a satisfactory pollen filter in the windows can be of help. If the patient is in an oxygen tent it is equivalent to air filtration. In fact, it is more satisfactory than most available filters.

3. If any foods have been found to be a cause of allergic symptoms, no matter how mild, they should be eliminated from the diet during the period when the patient has asthma, especially during the months when ragweed pollens are in the air.

4. Relief measures for asthma include (*a*) aminophylline, preferably by suppositories, may be used in 7½ grain (0.88 Gm.) doses, three to four times a day. Aminophylline may be given intravenously, very slowly, with observation for any untoward symptoms. The dose may vary from 3½ grains (0.52 Gm.) to 7½ grains (0.88 Gm.), depending on the tolerance of the patient, the rapidity with which the patient responds favorably to the injection and the severity of the attack. The smaller the dose the better. (*b*) Epinephrine solution 1 : 100, by inhalation with an all glass nebulizer, may be used for mild attacks. Treatment should be limited to every four hours. Epinephrine solution 1 : 1,000 may be injected carefully. It is not stated whether this patient has any hypertension. It is preferable to give the aqueous epinephrine solution subcutaneously in the minimum dose necessary for relief of symptoms, i. e., 0.2 to a maximum of 0.5 cc. every four to six hours. The ill effects of epinephrine solution given by injection, i. e., tachycardia or irregularity of rhythm or weakness and syncope, may readily be overcome if one uses a tight tourniquet distal to the point of hypodermic injection of epinephrine solution as soon as these symptoms appear. The tourniquet may be released in a minute to a few minutes with the disappearance of these symptoms and reapplied with the appearance of untoward symptoms. The absorption of epinephrine solution can thus be controlled. Untoward symptoms are unusual if the absorption is controlled for the first ten minutes. If epinephrine by injection in a dose as high as 0.5 cc. fails to give the patient relief from asthma, it must be discontinued for twenty-four to forty-eight hours and aminophylline and other measures used during that time until the patient again responds to epinephrine. Repeating the dose of epinephrine solution if the patient has failed to respond to the previous injection, unless one waits approximately forty-eight hours, may be harmful, especially in this case. (*c*) Sedation. One must make sure that the patient gets an adequate amount of sleep by the use of soporifics which are not respiratory depressants. The use of morphine or its derivatives during an attack of asthma is dangerous because of its tendency to cause depression of the respiratory center.

5. Specific treatment by a well trained specialist in allergy experienced in coseasonal treatment of pollen sensitivity and of mold sensitivity may be helpful.

## VISUAL EXERCISES

*To the Editor:*—Of what value is the Bates method of exercise and treatment given for cataract and other visual defects?

Mildred Doster, M.D., Washington, Iowa.

ANSWER.—Ophthalmologists are well aware that such treatments have their limitations and are by no means applicable to all eye defects indiscriminately. Such defects as cataracts, optic atrophy, corneal opacities and retinal lesions are not affected by such treatment. The important thing is that psychologic treatment may reconcile patients to defects, whether of the eyes, ears, legs or other parts of the body, and contribute enormously to the patient's comfort by teaching him how to become adapted to his condition. Doctors too often neglect this side of treatment. On the other hand, skilfully chosen exercises can improve visual functions. They form the basis of orthoptics. It is even possible to improve color discrimination, but impossible to cure color blindness. It is possible to teach myopic persons to make better use of their foggy vision without glasses, but not possible to reduce the myopia. It is possible to teach patients with opacities of the cornea like Aldous Huxley's to use their eyes more comfortably and contentedly, as he was taught and describes in his book. One hundred patients with cataract under competent ophthalmic supervision, as an experiment, were given treatment for one year, such as is recommended and used by various irregular practitioners. At the end of the year over 75 per cent said that they were better and wished to have the treatment continued. Tests with Snellen charts showed vision poorer in nearly every case, showing how unreliable is the patient's impression as to real visual improvement, how extremely important is the patient's subjective impression and how psychotherapy dominates successful treatment of the patient himself as distinguished from the patient's particular pathologic lesion.

## PHOTOSENSITIZATION

*To the Editor:*—A girl 8 years of age gives a history of being sensitive to light since the age of 3. Her symptoms appear in February, gradually becoming more pronounced until June or July. By the latter part of September apparently a reasonable degree of tolerance has developed, and the girl is then able to expose herself moderately without having a reaction. This child was given diphenhydramine hydrochloride ("benadryl hydrochloride") about two or three years ago. Her response to this medication was satisfactory for one season. Since then, "benadryl hydrochloride" and the other antihistaminic drugs have not produced results. This patient apparently has the ability to desensitize herself to a certain extent. Is there a method of maintaining this through the winter months?

R. S. Simenson, M.D., Manitowoc, Wis.

ANSWER.—The symptoms are not stated, but we can assume that the striking lesion is on the skin. Allergy is not the common cause of sensitiveness to light. In only a few cases has it been possible to transfer the reaction by injecting the patient's blood serum into the skin of a normal person and then demonstrating the reaction by exposure of the treated area. Such a test would be interesting here. In an excellent chapter on this subject, Urbach and Gottlieb distinguish exogenous and endogenous types of photosensitization. In occasional cases such drugs as the sulfonamide preparations or the barbiturates can lead to light reactions. Certain plants, like buckwheat and clover, can produce light reactions in animals. The topical application of sulfonamide drugs can also make the skin reactive to light in rare cases. The authors discuss the role of raw vegetables and raw meats in disturbing the metabolism of the porphyrins. Endogenous causes are more important, especially in adults. Hepatic disease is the major cause, but disintegrating tissue protein as in peptic ulcer, blood hemolysis or intestinal lesions, can also give rise to increased porphyrin in urine and stools. In this patient the diagnosis can be confirmed by exposing a small area of skin to the sun or to ultraviolet rays when the rest of the body is covered with a black cloth. For treatment, the child needs a careful and complete study to exclude the endogenous factors. Make the diet plain, avoid uncooked foods and be sure to eliminate drugs of every kind. Exposure to ultraviolet rays to maintain the tolerance through the winter can be tried, but it is not too successful.

Urbach, E., and Gottlieb, P. M.: Allergy, New York, Grune & Stratton, Inc., 1946, pp. 417-431.

## POLYARTHRITIS

*To the Editor:*—A white, female nurse, aged 26, complains of periodic low grade fever, stiffness and discomfort and swelling of fingers, hands and arms (with sensation of diffuse nodules in skin at times in her antecubital areas) which cause her to drop things at times. General malaise and tiredness occur during these episodes which recur regularly every few weeks. Her legs "feel like lead" on such occasions. Her first attack began during training four years ago with a temperature of 106 F. and swelling and pain of her right arm which lasted for two weeks and left her weak and drowsy for one week. Another sudden one, just involving the fingers, followed one year later; since then these have been recurrent. The patient has recurrent frontal headaches and some dysmenorrhea. The periods are regular and not excessive. The patient has had facial palsy since 6 weeks of age. She also has 2 brothers and 1 sister with similar history and appearance, in every case dating to infancy, when they would suddenly awake out of sleep with a shrill painful cry followed by this paralysis, which has persisted since. She had streptococcic sore throat six or seven years ago. Appendectomy was done in 1945.

The father and uncle have diabetes. A brother has heart failure.

The patient's physical examination elicited no abnormality findings except for those stated together with some coarsening of features. A pelvic examination was not done. There was no involvement of joints. The patient has had a basal metabolic rate ranging from minus 10 to minus 23 and is being given thyroid. The blood calcium is 17 to 24 mg. per hundred cubic centimeters; phosphorus, 2.92 mg.

During an attack the patient had a red blood cell count of 4,000,000 and a white blood cell count of 9,100, with 8 per cent eosinophils, 4 per cent stabs, 50 per cent segmented cells, 30 per cent lymphocytes and 8 per cent monocytes. Repeated heterophile antibody tests and undulant fever agglutination tests elicited negative reactions. Roentgenograms of the skull revealed marked hyperostosis of the frontal and parietal internal table, more marked in the anterior fossa, with excess bone density also along the base of the skull. The sella turcica bone and the humerus were normal. Biopsy of antecubital tissue was negative in result. Treatment with penicillin, streptomycin, diphenhydramine, was without effect. What are suggestions as to diagnosis and treatment? The patient has had a course of treatment for possible undulant fever. M.D., Missouri.

Answer.—This patient presents the clinical picture of recurrent, febrile polyarthritis; the most common cause of this in young persons is rheumatic fever. It would be of interest to know whether this was the cause of heart disease in the patient's brother. On the evidence available, it is not possible to exclude rheumatoid arthritis. The presence of subcutaneous nodules is characteristic of both diseases. Less common generalized diseases of the connective tissue which must be considered are lupus erythematosus disseminatus, periarteritis nodosa and dermatomyositis. The absence of cutaneous changes and hematuria and the negative biopsy render these unlikely, although the slight degree of eosinophilia is consistent with any of them. Gouty arthritis is a remote possibility.

The only observation not explained by any of these is the 17 to 24 mg. of calcium per hundred cubic centimeters of blood. Since this is one of the laboratory determinations most often found to be faulty, it should be repeated in another laboratory if possible. If it is confirmed, hyperparathyroidism must be considered and a careful history taken to exclude the possibility of vitamin D intoxication. The low basal metabolic rate is characteristic of any debilitating disease, and the hyperostosis frontalis interna is a common incidental finding.

Further studies which might be useful are: repeated determinations of serum calcium and phosphorus, serum alkaline phosphatase, serum albumin and globulin (in Boeck's sarcoid and in myeloma high serum calcium is associated with high serum globulin), urinary calcium excretion, erythrocyte sedimentation rate, response to therapeutic trial of salicylates and electrocardiographic studies.

## PERTUSSIS AND MEASLES IMMUNITY

*To the Editor:*—Please answer the following questions: 1. What is the status of human convalescent serum for pertussis? Is it effective in treatment in an active case? 2. Up to what age should infants be considered immune to measles? Below what age should human globulin not be given for exposure to measles? M.D., New York.

Answer.—1. There is not sufficient evidence to prove the value of human convalescent whooping cough serum. Moreover, pertussis convalescent serum is rarely available, but human hyperimmune serum can be obtained and is considered by many to be efficient. For passive immunity the serum should be administered as soon as possible after exposure. Human hyperimmune pertussis serum when given for treatment of whooping cough often seems to be beneficial.

2. If a mother has had measles, the disease is uncommon in her offspring before 6 months of age and is rare under 4 months. Because most adults have had measles during the first years of life there is conveyed to the infant a transient immunity which usually endures for from four to six months after birth. Therefore, it is not necessary generally to give human immune globulin prior to 4 months of age, but there is no serious objection to doing so.

## PHYSICAL ALLERGY

*To the Editor:*—A patient, age 21, unmarried, experiences intense itching of the skin all over the body immediately after a shower or tub bath, either hot or cold water. Water in different parts of the country causes the same effect. The reaction occurs during warm weather but not during cold weather. Mere dampness in the air excites itching in a mild manner. It is apparently not related to menstrual periods; however, menstrual cycles are somewhat irregular. She is somewhat obese. Blood pressure and routine laboratory tests reveal nothing noteworthy. Antihistaminics have been tried in bold dosage, without avail. Allergy to foods or pollens is absent. Please advise treatment. M.D., Alabama.

Answer.—The patient described appears to have an abnormal response to temperature change, called "physical allergy." While most of such cases of thermal hypersensitivity are due to cold and a lesser number are due to heat, a third group reacts to both cold and heat. Usually urticarial lesions accompany the phenomenon, but itching may be frequent without evident lesions. The mechanism is commonly accepted as an increased tendency to release large amounts of histamine from the tissues exposed to the thermal stimuli. Humidity aggravates the condition, because the temperature is more penetrating when the percentage of humidity is high than when the air is dry. It is not easy to understand why the syndrome does not occur in cold weather. Possibly the colder weather induces an increased tolerance.

The inquirer might try to reproduce the syndrome by exposure to cold or heat and note any blood pressure change. A decided fall in blood pressure would speak for a histamine release. The management of these cases is not easy. The antihistaminic drugs frequently fail, perhaps because of the fact that the amount of histamine liberated is too great to be combated by the amount of antihistamine drug reaching the skin sites. Several procedures are worthy of trial. One is a daily exposure to cold followed by heat. This may be in the form of an immersion of the hand and forearm in water at temperature of 50 F. for about four minutes twice daily, followed by exposing the extremities to warm water. In some patients frequent injections of small doses of histamine may result in improvement. This consists usually of histamine of 1:100,000 or 1:10,000, subcutaneously, once or twice daily. The mechainism of this is not known, although it is certain that it is not due to a production of greater histamine tolerance. Another method of approach is the use of nonspecific injections or fever therapy.

## NITROGEN DETERMINATION: NESSLER METHOD

*To the Editor:*—I have had difficulty doing a nonprotein nitrogen determination of the blood according to the Folin and Wu method. I am using a Leitz colorimeter. The values are always too high. When Nessler's solution is added the resultant mixture becomes too dark. I am using fresh solution. Please supply information.

Abraham Shedlov, M.D., Fosston, Minn.

Answer.—There are several possibilities of error in the determination of nitrogen by the Nessler method, which must be avoided if accurate results are to be obtained:

1. The Nessler's reagent must be carefully prepared and must stand undisturbed in a dark bottle until the solution has become completely clear. This usually requires three to four weeks, but the solution appears to improve with further aging. The sediment should not be disturbed in withdrawing solution, and siphoning is the preferred technic for removing solution from the stock bottle.

2. The alkalinity of the final reagent must be within the limits given in standard laboratory manuals.

3. The Nessler's solution must be added rapidly, preferably from a graduate, to a cold solution, and the two should be mixed immediately with further cooling if necessary.

4. The final solution must be sparkling clear since turbidity completely obviates photometric determination of color intensity. The simplest test for turbidity is viewing the solution through the length of the tube. In clear solutions the bottom will be clearly seen, while in turbid solutions the bottom of the tube cannot be seen.

5. The quantity of nitrogen in the sample should be between 0 and 0.1 mg. expressed as nitrogen. Quantities of nitrogen above this range are prone to give turbid solutions.

## ACETYLSALICYLIC ACID IN PREGNANCY

*To the Editor:*—Does acetylsalicylic acid act similarly to quinine during pregnancy in stimulating uterine contractions? If so, is this action likely to be encountered in equal measure throughout pregnancy, or is it more marked at certain stages of gestation? M.D., China.

Answer.—The literature apparently contains no evidence which tends to show that acetylsalicylic acid causes uterine contractions.

## RECURRENT ERYSIPELAS

*To the Editor:*—What is the latest information on treatment of recurrent erysipelas? A 52 year old man had his first attack in 1941 with reddening of the inner side of the leg and swelling of the lymph nodes on the same side. At the beginning, the attacks recurred in intervals of two weeks. Later, the periods of freedom from attacks became longer—the longest lasting up to one year. During these years the patient was advised to treat the skin of the leg by bathing with potassium permanganate solution alternating with sulfathiazole ointments. After the longest remission, of one year, he suddenly had attacks again in intervals of three to five or six weeks. Fever which accompanied these attacks responded quickly to sulfadiazine. Trial with penicillin has not brought any change. Would you advise use of streptomycin or other procedure? Roentgen treatments as well as protein therapy have been unsuccessful. The patient has athlete's foot and is constantly treated for this condition in the belief that it may be a predisposing factor. He is in perfect health otherwise, with the exception of moderately enlarged veins of both legs.

Egon E. Lustig, M.D., New York.

ANSWER.—This is a difficult therapeutic problem. The difficulty is apparently an immunologic one, the patient having a heightened susceptibility toward some organism, probably, but not necessarily, a hemolytic streptococcus. Three lines of attack should be tried, although none of them offer too great a promise of cure: 1. Foci of infection anywhere in the body should be searched for and eradicated. 2. Cultures should be made from the skin at the times of the attacks and vaccines made from these organisms. A course of vaccine injections may be tried with the hope of hyposensitization. 3. More attention should be paid to the patient's dermatophytosis. This should be under continuous therapy with some of the newer fungistatic agents, such as mixtures of undecylenic acid and zinc undecylenate, assuming these to be well tolerated. Intradermal tests with trichophytin should be performed, and if the patient exhibits pronounced reactivity desensitization might also be tried.

The susceptibility of the cultured organisms to streptomycin could be determined, but it is not felt that a course of this or any other antibiotic will provide a permanent cure. None of these measures hold real promise of success; nevertheless, they should be tried because, if attacks continue, they may lead to fibrotic changes with ensuing lymphedema.

On the theoretical side the correct diagnosis in this case is by no means certain. The case may be one of orthodox recurrent erysipelas or it may be a recurrent erysipelas-like eruption. In this event the causal organism could be anything, but the most likely nonstreptococcic cause is a sensitization to a fungus, especially Trichophyton. If this is so the eruption is a recurrent erysipelas-like trichophytid. The literature on this has been well discussed in two answers in Queries and Minor Notes, THE JOURNAL, July 10, 1943, page 77, and March 7, 1947, page 655.

## DEPILATORIES

*To the Editor:*—Kindly outline the rational treatment of hypertrichosis (superfluous hair) of the face. Please name the best depilatories, indicating the ingredients and their doses.

F. Stuczynski, M.D., Brooklyn.

ANSWER.—The only safe method for permanently removing superfluous hair is by electrolysis. Depilatories are temporary methods of removing hair and must be repeated every ten to fourteen days. Barium sulfide or a mixture of calcium and barium sulfide are chiefly used. The depilatories appear in powder form or may be sold as semisolids. If in powder form, the preparation is mixed with enough water to form a paste that is easily applied to hair regions. It is allowed to remain on the skin until dry and then washed off. The hairs come off in the washing. Andrews recommends the following formula:

| | |
|---|---|
| Calcium sulfide | 1 part |
| Water (to make paste) | |
| Zinc oxide | 3 parts |

This may be irritating, and the label should include the ingredients and a word of caution.

Mix into a paste with a little water, rub on the skin for five minutes. Scrape off softened hairs with the edge of a tablespoon; wash the skin. Apply a soothing lotion, such as calamine lotion.

McCarthy recommends the following paste:

| | Gm. or Cc. |
|---|---|
| Barium sulfide | 10 |
| Zinc oxide powder | 12 |
| Starch | 12 |

Keep container tightly closed. When ready to apply, add sufficient water to make a paste and leave on two minutes before scraping off. Apply a soothing cold cream to allay irritation. This application should be repeated every ten to fourteen days.

Roentgen therapy is mentioned here to condemn it because of its dangerous sequella. Depilatory creams with thallium salts also are condemned because of their toxicity.

## CONDYLOMA LATUM

*To the Editor:*—A 20 year old female patient was seen June 1947 for secondary syphilis, with typical macular eruption on the palms of both hands. The Kline reaction was 4 plus and quantitative Kahn 120 units. Spinal fluid was negative after three weeks of therapy. The patient was given fourteen consecutive daily injections of penicillin, Romansky formula 300,000 units each, along with oxophenarsine hydrochloride (mapharsen) 0.06 Gm. twice weekly for twelve injections, plus 1 cc. (2 grains) of bismuth compound every five days, for a total of twelve injections. The quantitative Kahn reaction has returned to negative after one year. The Kline diagnostic and exclusion reactions remain positive. Spinal fluid July 1, 1948, was normal with a cell count of 1, negative Wassermann, colloidal gold and globulin reactions. Physical examination revealed no abnormalities except for fairly severe and extensive condyloma accuminata about the vulva and anus, of two weeks' duration. In the face of an apparent return to normal of reactions to quantitative Kahn made at two-months intervals, I cannot explain the occurrence of the condylomas on a syphilitic basis. Evidence of other venereal infection is lacking. I plan to treat the condylomas with resin of podophyllum but am hesitant as to whether or not they are syphilitic. All tests were done at the same laboratory.

M.D., Ohio.

ANSWER.—Condyloma accuminatum is not due to syphilis; condyloma latum is due to syphilis. The latter occur as a manifestation of the so-called secondary stage of syphilis, when, by all the rules, the serologic test of the blood should reveal a strongly positive reaction with a high titer. In this case the history of adequate treatment followed by a serologic curve in which the Kahn quantitative titer decreased steadily, until the reaction became and remained negative, would indicate that the patient's syphilis is "cured" and that her condylomas are the nonsyphilitic accuminate type. Treatment with resin of podophyllum is well worth a trial in this case. The blood should be checked at regular intervals for about five years more and, if the Kahn reaction continues to be negative, no further antisyphilitic treatment will be necessary.

## TRAUMATIC PITUITARY NECROSIS

*To the Editor:*—I am unable to find literature which mentions pituitary necrosis secondary to trauma. We have recently had a case of basal skull fracture, in which death occurred five days after injury. Autopsy findings revealed the fracture line passing through the pituitary fossa with a blood clot surrounding the pituitary gland. Microscopic examination reveals areas of necrosis.

Harry J. Schneider, M.D., French Camp, Calif.

ANSWER.—Munslow, Haymond and Crawford (*Arch. Path.* **34**:431-434 [Aug.] 1942) reported the case of a man who died three hours after injury to his head. A basal skull fracture, which extended into the sella turcica, and areas of hemorrhage into the substance of the posterior lobe of the pituitary body were found on necropsy. In this article references are given to reports of similar cases observed by Simmonds, Schmorl and Cushing. Reverchon, Worms and Rouquier reported a case (*Presse méd.* **29**:741-743 [Sept. 17] 1921) in which sclerosis and atrophy of the pituitary body were found several months after a basal skull fracture. It would not be unreasonable to assume that the period of survival after injury might determine whether hemorrhage, necrosis or fibrosis and atrophy would be the predominating histologic characteristic.

## FLUORESCENT LIGHTING

*To the Editor:*—What are the advantages and disadvantages of fluorescent lamp illumination for the classroom?

Dorothy Donley-Dowd, M.D., Washington, D. C.

ANSWER.—Fluorescent lighting has the advantage of costing less per candle so that more light is furnished per dollar of cost. It is easy to install it so that there will be minimum of glare. It gives less heat, which is sometimes important in hot weather.

Most of the complaints are traceable to improper installation, and therefore improper distribution of the light. There is some uncorroborated evidence that exposure to fluorescent lighting reduces dark adaptation unduly.

## IMMUNIZING INJECTION INTERVALS

*To the Editor:*—In immunization of infants with the triple vaccine, pertussis, diphtheria and tetanus, mixtures how long can the intervals between injections be lengthened before it is advisable to start the series over again?

Abraham D. Cohen, M.D., New York.

ANSWER.—Even though the intervals are two to three months, a satisfactory degree of immunity may follow the final injection. The antibody response to prophylactic injections is not identical in all persons. Hence the optimum for injections is not always easy to determine.

## HYDROCEPHALUS

*To the Editor:—A young woman had a full term, hydrocephalic stillbirth as the result of her first pregnancy. Her general health is excellent. History of virus infection during pregnancy, radiation therapy, trauma, syphilis and other known complicating factors are absent. What is the probability that hydrocephalus or other anomalies will occur in subsequent pregnancies?*

M.D., New York.

Answer.—The possibility of the occurrence of hydrocephalus in the subsequent children of a woman whose first child suffered from this condition cannot be denied, but it is uncommon. Usually when one child has a hydrocephalus the other children are normal. Grulee and Bonar (The Newborn; Diseases and Abnormalities, Clinical Pediatrics Series. New York, D. Appleton & Co., 1926) mention the possibility of hydrocephalus occurring in several members of the same family. In general, unless there is a family history to the contrary, it is advisable to reassure patients that in having additional children they run no greater risk that subsequent children will be similarly affected than do all other parents.

## ACTINOMYCOSIS

*To the Editor:—A young man on the plains of Colorado picked up a small pebble to roll around in his mouth. Later his left jaw began to enlarge. The condition was diagnosed as actinomycosis. He was operated on several times, which has to a certain extent deformed his jaw. He has had x-ray treatment until all the hair on that side of his head has disappeared. Once in a while nodules form on the left side of his head, above his ear. He is otherwise healthy. I am using compresses of bichloride 1:1,000 on the side of his head, night and morning, and intravenous injections of oxophenarsine hydrochloride. The larger nodules have softened, and some have disappeared under this treatment. Can you suggest anything that might be of benefit?*

M.D., California.

Answer.—An accurate diagnosis should be made by demonstrating actinomycetes in the purulent discharge from the lesions. If the condition is actinomycosis, the best treatment is 1,000,000 units of penicillin daily for three weeks. It may be necessary to repeat this treatment after an interval of three months.

## MILK DIET

*To the Editor:—A machine shop worker, 71 years old and apparently well, drinks 4 quarts of milk every day. May his intake of calcium be harmful?*

M.D., Massachusetts.

Answer.—Serious elevation of the serum calcium does not occur even under the most favorable conditions for absorption unless an excess of vitamin D or parathyroid hormone is present. Overdosage of these may raise the serum calcium to abnormally high levels and result in metastatic calcification and other toxic effects. Excess calcium is excreted. Apparently the patient will not suffer any deleterious effects from the consumption of the calcium contained in four quarts of milk (approx. 4.5 Gm.), but the increased fluid intake should have consideration.

## IMMUNITY TO SNAKE BITE

*To the Editor:—A statement was made in a group discussion that pregnant women are immune to rattle snake venom. The physician stated that he practiced in a rattle snake country where such bites were frequent. He said that all the doctors in that territory knew this and did not believe it necessary to give anti-venin if the victim were a pregnant woman. Is this true?*

F. L. Chenault, M.D., Decatur, Ala.

Answer.—It is unlikely that a pregnant woman would be immune to rattle snake venom. This query was discussed with several well known authorities on toxic properties of venoms such as Dr. Goss and Mr. Brayton Eddy, Curator of Reptiles of the New York Zoological Society. Also, the matter was discussed with Dr. Bogert, Herpetologist at the American Museum of Natural History. They all agreed that such a possibility was unlikely. Colonel Crimmins, the well known authority on snake venoms, also concurs with these opinions.

## MYELOGRAMS

*To the Editor:—Of what use are myelograms for diagnosis of injuries of the back and what is the incidence of increased pain in the back following studies of this kind?*

J. M. Hesser, M.D., Benson, Ariz.

Answer.—Localization of intraspinal lesions such as protruded intervertebral disks, neurofibromas or other tumors can be most accurately obtained by the use of myelograms. Opaque mediums, which are relatively nonirritating and may be absorbed if not removed, such as "pantopaque" (ethyl iodophenylundecylate), can be used safely and without causing increased pain in the back.

## ENDOMETRIOSIS

*To the Editor:—In the June 5 Journal is a query by Dr. M. Karasek on endometriosis. I read the answer with a great deal of interest because the statement is made, "Therefore, the use of estrogen is usually contraindicated in any phase of this disease."*

*I have been experimenting with testosterone propionate in endometriosis for three years and have never caused endometrial implants to disappear completely, but after changing over to estrogen (diethylstilbestrol), giving large and increasing doses for six to nine to twelve months, my associates and I have found by biopsies and by repeated pelvic examination and culdoscopy that in patients taking such doses of diethylstilbestrol endometriosis was caused to atrophy completely if the drug was continued long enough. After discontinuance of diethylstilbestrol some of the patients became pregnant and some had children.*

*The advantages of diethylstilbestrol over male hormones are that there is no development of hirsutism or coarseness of voice. There is nausea when the patient starts to take the drug, but that will pass off in four to five days if the drug is continued.*

*The recommended dose is 0.5 mg. for three nights, 1.0 mg. for three nights, 2.0 mg. for three nights, 3.0 mg. for three nights, 4.0 mg. for three nights, 5.0 mg. for three nights, 10.0 mg. for three nights, 15.0 mg for three nights, 20.0 mg. for three nights, and every third night an increase of 5 mg. If the patient bleeds, give 25 mg. to 50 mg. every fifteen minutes until the bleeding stops. Do not let the patient bleed for three to six to nine months, according to the severity of pain and the extent of the endometriosis.*

*I recommend this treatment for use after cancer has been ruled out in many cases instead of surgical or roentgen treatment. Given presurgically it makes surgery easier because of atrophy of ovaries. Diethylstilbestrol may be given to patients with associated disease that must be removed. When diethylstilbestrol is discontinued the patients usually return to normal menstruation, ovulate and are free from almost all pain.*

*Karl John Karnaky, M.D., Medical Arts Bldg., Houston, Tex.*

## ERYTHROBLASTOSIS

*To the Editor:—We feel it necessary to correct the misunderstanding which is likely to arise from the answer given in your queries page to Dr. R. E. Heerens' question regarding spasticity following apparently cured erythroblastosis fetalis (The Journal, October 2, page 394).*

*It is stated here that there is "an extremely high incidence of infantile jaundice and blood incompatibility among children suffering from mental deficiency, athetosis, spasticity and other cerebral defects of early infancy." The data presented in the articles given as references for this statement do not justify such a generalization. Actually (Yannet, H., and Lieberman, R.: J. A. M. A. 130:335-340 [Feb. 9] 1946) it was found that in a group of one hundred and nineteen mental defectives classified as "undifferentiated," in that there was no clearly indicated etiology or typical clinical picture (such as mongolism), the probable incidence of damage due to Rh blood group incompatibility was not higher than 8 per cent.*

*In short, the study referred to indicates that an appreciable but small number of "undifferentiated" mental defectives will have a background of blood group incompatibility with respect to the Rh factor.*

*It is not to be inferred from this that the incidence of cerebral damage is high in erythroblastotic infants who have made an apparently satisfactory response to treatment in the newborn period. The reverse is true. The incidence of subsequent cerebral defect in infants surviving erythroblastosis fetalis in the newborn period is only about 8 per cent. This need not be considered a serious risk by mothers sensitized to the Rh factor who want to try to enlarge their families, although the occurrence of a badly damaged child may be tragic in any individual instance.*

*It is our belief from personal observation of many such infants that the clinical signs of brain injury are uniformly present in the first week of life in babies destined to be defective in the future, and that the signs are unmistakable in most instances. They consist mainly of varying degrees of lethargy, opisthotonos, and spasms of rigidity, typically occurring with arms extended and inwardly rotated and fists clenched. If an infant examined daily by an experienced observer survives the first week without showing such signs, prognosis for future normal development is excellent.*

*Finally, it should be mentioned that the future development of some babies with brain damage due to erythroblastosis fetalis may be surprisingly good. Ultimately normal function will occasionally be seen in a child more or less severely handicapped in early infancy, particularly when the defect seems largely confined to the motor system.*

*Victor C. Vaughan III, M.D.*
*Fred H. Allen Jr., M.D.*
*Louis K. Diamond, M.D.*
*Boston.*

## SUBSTERNAL PAIN

*To the Editor:—In Queries and Minor Notes in the July 17, 1948 Journal, page 1097, under the title "Substernal Pain," the question was raised whether sea food is poor in cholesterol. In addition to the data by R. Okey included in your answer, I submit further analytical data which may be of interest.*

*As the dietetic importance of canned fish is increasing steadily, my associates and I investigated the total cholesterol content of canned fish by the method of Sperry and Brand and Sobel and Meyer, and found the following values. Values are expressed on the basis of dry substances:*

| Fish | Percentage | Fish | Percentage |
|---|---|---|---|
| Yellowfin tuna........ | 0.149 | Pacific mackerel ....... | 0.24 |
| Bluefin tuna ........ | 0.172 | Horse mackerel ........ | 0.27 |
| Albacore ............ | 0.144 | Sardines .............. | 0.19 |
| Skipjack ............ | 0.180 | | |

*In comparison with the values for round beef (0.4 per cent), veal shank (0.5 per cent), calf liver (1.42 per cent), whole egg (1.8 per cent), the cholesterol content of canned fish seemed to be particularly low.*

# SYMPTOMATIC TREATMENT OF CERTAIN TYPES OF CHRONIC HEADACHE

ARNOLD P. FRIEDMAN, M.D.
CHARLES BRENNER, M.D.
and
SIDNEY CARTER, M.D.
New York

Headache is a symptom which is found in a variety of conditions. Two of the commonest syndromes in which it plays an important role are those associated with trauma and the reaction patterns expressed in psychoneurosis. In our clinic these two types of headaches far exceed all other groups in number.

Because of the lack of unanimity with respect to diagnostic criteria in the classification of various types of chronic headache, we wish first to present and discuss briefly the criteria used in this study.

Patients classified as having post-traumatic headaches fulfilled the following criteria: the headaches of which they complained appeared after head trauma and persisted for longer than two months following the trauma.[1] No attempt has been made in the present study to subdivide this group of patients further in any way for purposes of statistical analysis and comparison, e. g., open versus closed injuries and duration of coma after injury.

Considerable difference of opinion exists as to the nature of the most important factors in the causation of post-traumatic headaches. A summary of the views of many authors[2] reveals essentially three opinions. Some consider the causative factors to be exclusively psychologic, some to be exclusively physiologic and some to be composed of both factors. The latter view has been emphasized previously by us[1] and appears to be supported by the greatest weight of the evidence presently available.

The physiologic mechanisms which are presumably involved in the production of post-traumatic headaches are: (1) distention of cranial blood vessels, (2) sustained contractions of the skeletal muscles of the head and neck and (3) scarring of the extracranial soft tissues.[3] Psychogenic factors include the immediate emotional effect of the injury (e. g., anxiety, depression, resentment or frustration), the pretraumatic neurotic tendencies or conflicts of the patient and the psychic conflicts due to the environmental stresses incident to the injury.

Patients classified as having psychogenic headaches fulfilled the following criteria: their headaches regularly occurred in conjunction with psychic conflicts or situations of psychic stress; physical and laboratory examinations revealed no evidence of physical illness or anomaly which might be expected to produce headaches; there was no history of immediately antecedent trauma, and the symptoms were not those of true migraine.[4]

The ways by which such psychologic conflicts or stress result in the physical symptom of headache often (perhaps regularly) involve the operation of certain physiologic mechanisms. Such mechanisms include changes in the caliber of the cranial vessels (probably chiefly vasodilatation) and spasm or tonic contraction of the skeletal muscles of the head and upper cervical region.

There appears to be a wide diversity of opinion as to the value of each of the multitude of remedies that has been proposed for the treatment of these types of headaches. The present study was undertaken to assess and compare the effects of representative drugs under conditions which were as carefully controlled as possible.

## MATERIAL AND METHODS USED

Two groups of patients are included in this study: those attending the headache clinic at a large general hospital and those attending a veterans' clinic. The former group consisted of both male and female subjects and were of all ages. The latter group was composed entirely of male subjects, for the most part between the ages of 20 and 40.

---

Aided by a grant from the Schering Corporation.

Psychologic testing was done by T. Johnson, Veterans Administration.

This work was done under a grant from the Virginia M. Rosenthal Fund, Montefiore Hospital.

Electroencephalographic examinations were made by Margaret B. Rheinberger, Ph.D., and A. L. Deutsch, M.D.

Read before the Section on Nervous and Mental Diseases at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

Presented with permission of the Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for the opinions expressed or conclusions drawn by the authors.

4. Friedman, A. P., and Brenner, C.: Treatment of the Migraine Attack, Am. Pract. **2:** 467, 1948.

Five hundred and twenty-one patients were treated over a period varying from two months to three years. The number falling in each of the diagnostic classifications is shown in table 1.

The general principles of treatment which were followed were those previously described.[5] A majority of the patients received a combination of simple psychotherapy and pharmacotherapy, while a smaller group was given psychotherapy alone. The drugs used included analgesics (acetylsalicylic acid; acetylsalicylic acid, acetophenetidin and caffeine; acetylsalicylic acid with i-amylethyl barbituric acid; acetylsalicylic acid with caffeine; and diethylcinnamamide[6]; vasoconstrictors (ergotamine tartrate; ergotamine tartrate with caffeine[7]; dihydroergotamine methane-sulfonate[7]; and ephedrine with i-amylethyl barbituric acid), vasodilators (sodium nicotinate; nicotinic acid, and 2-benzyl-4,5-imidazoline hydrochloride ["priscol"][8] alone and with caffeine), hormones (testosterone propionate[6] and alpha-estradiol benzoate[6]) and hormones combined with vitamins (testosterone propionate with vitamin B).

## RESULTS

In a group of 334 patients with psychogenic headache there were 286 trials with analgesics, 165 trials with vasoconstrictors, 135 trials with vasodilators, 104 trials with a combination of hormones and vitamins and 86 trials with inactive substances ("controls"), either placebos by mouth or parenterally administered isotonic sodium chloride solution. The results are summarized in table 2. It should be mentioned that there was no significant difference between the results obtained by administration of inactive substances orally or parenterally.

TABLE 1.—*Number of Patients with Headache and Their Classifications*

| Type | No. of Patients |
|---|---|
| Psychogenic | 334 |
| Post-traumatic | 187 |
| Total | 521 |

From table 2 it appears that the best results in this group of patients was obtained by the administration of analgesics and that the other types of medication were no more effective than the inactive substances used.

One hundred and eighty-seven patients with post-traumatic headache were treated. In this group there were 164 trials with analgesics, 85 trials with vasoconstrictors, 92 trials with vasodilators, 45 trials with a combination of hormones and vitamins and 43 trials with inactive substances, all of which again are listed in the accompanying table as "controls," since there was no difference between the results obtained by administering them orally or parenterally. The results of treatment for this group of patients are summarized in table 3.

Again it appears that the best results were obtained by the administraion of analgesics and that the other types of medication were no more effective than the inactive substances.

Psychologic tests and electroencephalograms were also performed on many of these patients with post-traumatic headache who are included in this study as well as others who are not included for reasons of incomplete follow-up. A thorough analysis of the results of these special examinations is still under way, but it is possible to report at this time that the electroencephalograms of 258 patients with post-traumatic headache failed to show any higher percentage of abnormalities in frequency range than would be expected in a random sample of the population. Furthermore, psychologic tests in patients with post-traumatic headache (Wechsler-Bellevue and/or Rorshach) did not reveal any significant differential pattern on the basis of evaluating the entire group tested.

TABLE 2.—*Results of the Use of Drugs in Patients with Psychogenic Headache*

| | Analgesics | Vasoconstrictors | Vasodilators | Hormone and Vitamin | Control |
|---|---|---|---|---|---|
| Patients improved (percentage) | 71 | 49 | 51 | 58 | 57 |
| Patients not improved (percentage) | 29 | 51 | 49 | 42 | 43 |

## COMMENT

The effectiveness of drug therapy in the treatment of psychogenic and post-traumatic headaches was influenced by many factors. To begin with, the patients attended a clinic devoted exclusively to the problem of headache. Complete studies, including roentgenograms of the skull and [illegible] were done before any medicatio[illegible] roughness of the investigation was in itself a psychotherapeutic procedure in many cases. After the medication was started, the patient returned to the clinic at regular intervals at which time some form of psychotherapy was given. The effectiveness of the medication depended to some extent on the physician prescribing the medication, the time he spent with the patient and the frequency with which the patient was seen by him. We noted in many cases that patients would maintain a state of improvement if they were seen at weekly intervals but would have a recurrence of headache if they were seen at monthly intervals instead. In addition, the factors of disability compensation and litigation played a part in many of the cases of post-traumatic headache.

Fifty to 60 per cent of the patients with psychogenic and post-traumatic headache responded favorably to almost any medication given them. The analgesics and some of the oral placebos were taken only at the time of the headache, while the hormone-vitamin combination and the isotonic sodium chloride solution were given by injection at regular intervals. The effect of medication given by injection in cases of psychogenic illness is too well known to require further discussion here. In addition, several of the patients receiving the combination of hormones and vitamins reported a feeling of well-being that undoubtedly played some part

TABLE 3.—*Results of the Use of Drugs in Patients with Post-Traumatic Headache*

| | Analgesics | Vasoconstrictors | Vasodilators | Hormone and Vitamin | Control |
|---|---|---|---|---|---|

in their improvement. The similarity of response obtained with the various medications in psychogenic and post-traumatic headache (table 4) again emphasized the close relationship between these two types of headache.

Psychotherapy alone seemed to be slightly less effective than the combination of psychotherapy and pharmacotherapy in the treatment of psychogenic headache, even though the patients in this group were specially selected as promising candidates for psychotherapy (table 5). This result is perhaps somewhat influenced by the fact that the majority of the patients were seen for psychotherapy during clinic hours in a busy clinic. One of us was able to see 9 of the 27 patients in this group by appointment in his private office. Seven (77 per cent) were improved, as compared with a 50 per cent improvement in the other 18 patients.

| Psychogenic | 57 | 43 |
| Post-traumatic | 63 | 37 |

Table 5.—*Comparison Between the Effect of Psychotherapy Alone and Psychotherapy Plus Pharmacotherapy in Patients with Psychogenic Headache*

| | No. of Patients Improved (Percentage) | No. of Patients Not Improved (Percentage) |
|---|---|---|
| Psychotherapy | 59 | 41 |
| Psychotherapy plus analgesics | 71 | 29 |

## CONCLUSIONS

Five hundred and twenty-one patients with psychogenic and post-traumatic headaches were treated, 494 by a combination of psychotherapy and pharmacotherapy and 27 by psychotherapy alone.

The drugs used included analgesics, vasoconstrictors, vasodilators, hormones combined with vitamins, placebos and parenterally administered isotonic sodium chloride solution.

The best results in each group of patients were obtained by the use of analgesics. The other drugs gave no better results than those obtained by the use of inactive substances.

The results we have reported strongly suggest that in cases of psychogenic and post-traumatic headaches the effectiveness of symptomatic treatment is primarily caused by the patient's psychologic reaction to the treatment situation in general and in particular to having received a "remedy" from the physician. Evidence for this is the fact that almost equally good results were obtained by the use of placebos.

The similarity of results of drug therapy of patients with post-traumatic and psychogenic headaches suggest that the mechanisms of production of the two types of headache are closely related and probably are similar responses of the body to disturbing psychologic stress.

## ABSTRACT OF DISCUSSION

Dr. Pearce Bailey, Washington, D.C.: The studies of Dr. Friedman and his colleagues tend to clarify the subject of post-traumatic and psychogenic headaches. This problem, particularly post-traumatic headache, was a perplexing one during two world wars, and it is gratifying to see that Dr. Friedman's investigations include follow-up studies of veteran patients. In military psychiatric and neurologic practice, much of the difficulty concerning post-traumatic headaches arose from an inclination on the part of many medical officers to label this complaint as either organic or psychogenic rather than to evaluate both longitudinally and in cross section the total physiologic and psychologic reactions of a person to a traumatic situation, as has been done by Dr. Friedman and his colleagues. This propensity often led to helpless indecision, both as to the therapy and ultimate disposition of these patients. In a large naval hospital, I had occasion to examine about 200 patients with headache following head injury. Only a few of these appeared to suffer from a purely organic disability devoid of any psychologic coloring. This is comprehensible, since these injuries were usually sustained in circumstances contributory to severe psychologic reactions, namely: (1) a pretraumatic period of fatigue and prolonged emotional stress, (2) a traumatic episode which threatened the integrity of the head and (3) a post-traumatic period of confusion and/or panic leading to defense mechanisms against a recurrence of the traumatic experience by the establishment of a true disability, with consequent discharge from the service and possible monetary reward in the form of pension or retirement benefit. No exact statistical study was made of our group of patients with post-traumatic headache, but the patients were roughly classified into several categories, according to the quantity and quality of their psychobiologic reactions. There was, of course, considerable overlapping of the categories. By far the largest group was characterized by a history of normal pretraumatic personality development, whose emotional reserves had become depleted from prolonged combat and in whom the head injury served as a precipitant for emotional disorganization. Here the picture was one of panic or acute anxiety, headache, startle reaction, battle dreams and sympathetic overstimulation with or without objective evidence of structural damage to the nervous system. The headache was subordinated to the over-all distress and would rise and fall in synchronization with the general tension. These patients abreacted intensely to combat scenes in interviews with "amytal" (5-isoamyl-5-ethylbarbituric acid) anesthesia and were helped by psychotherapy, and some were even returned to duty.

Dr. Arnold P. Friedman, New York: We have found that patients suffering from both psychogenic and post-traumatic headaches vary in their reaction patterns. Some show evidence of conversion hysteria; others show schizoid tendencies and compulsions. Our experience has been that psychotherapy combined with drug therapy is much more effective than drug therapy alone in reducing the frequency, duration and severity of the types of headaches we are discussing. To overlook or fail to treat the psychologic conflicts in a patient with chronic headaches of these types is to run the risk of therapeutic failure. Analgesics (salicylates or acetophenetidin) combined with short-acting barbiturates seem to be the best medicaments for these types of headaches. The analgesic acts by raising the pain threshold, and the sedative action of the barbital decreases the tension. In some cases, precipitating psychologic factors may be rather superficial and the patient does not need profound therapy; in others, it may be rather difficult to uncover the dynamics of the mental processes involved which are causing or precipitating the headaches. If the problem is mainly one of environmental difficulties, we find social agencies to be of extreme value. I have been asked to name some effective analgesics. In this group codeine raises the pain threshold the highest, but in general acetylsalicylic acid and acetophenetidin usually suffice.

# THERAPY OF MIGRAINE

ROBERT M. MARCUSSEN, M.D.
and
HAROLD G. WOLFF, M.D.
New York

The therapy of migraine falls into two categories; treatment of the individual attack of headache and prevention of, or reduction in, the frequency and severity of recurrences. Migraine is a syndrome with certain easily identifiable features and a variety of associated phenomena. Characteristically, it is a periodic headache which is unilateral in onset, but which may become generalized. It may be preceded by visual disturbances, paresthesias in the extremities or speech disorders. With the headache there may be irritability, photophobia, nausea and vomiting. The attack may be followed by a feeling of especial well-being, and the patient is usually free of disagreeable head sensations between episodes. The headache itself is the end manifestation of a chain of bodily changes set off by pernicious emotional states. This head pain is associated with dilatation of certain pain-sensitive arteries inside and outside the head. The prodromal phenomena, scotomas, paresthesias and the like, arise from constriction of arteries in strategic areas of the brain. It is possible that painful vasodilatation represents an abortive attempt on the part of the body to compensate for this vasoconstriction and restore the homeostasis of cranial circulation.

## TREATMENT AND PREVENTION OF ATTACKS

Because of its dramatic, disabling nature, the physician is most frequently called on to deal with this pain. The most potent agent available for the constriction of these painfully dilated cranial arteries is ergotamine tartrate. It is most effective intramuscularly in doses of 0.25 to 0.50 mg. as early as possible after the pain appears. The patient should be taught how to give himself the medication so that he can get it within the first half hour of the headache. As an alternative, four 1 mg. tablets should be taken sublingually as soon as possible after the beginning of the headache, followed by two such tablets every half hour until a total of 10 mg. has been given in an hour and a half. Dihydroergotamine (DHE 45), an ergot derivative said to have fewer of the undesirable side effects of ergotamine, is useful but less effective in intramuscular doses of 2 to 4 mg.

Ergotamine tartrate relieves headache within an hour in 80 per cent of cases. When this fails, drugs which raise the pain threshold should be used. The most satisfactory of these is codeine phosphate, 60 mg. orally, or hypodermically when vomiting interferes with absorption. Morphine and newer synthetic analgesics should be avoided because of the danger of addiction.

Amobarbital sodium ("amytal sodium") 0.2 Gm. by mouth, given at the same time as the ergotamine, will insure rest and relaxation, an integral part of treatment. An ice cap to the head is comforting. Bed rest in a quiet, darkened room is essential during the pain and for at least an hour after the pain has subsided.

Many investigators have advocated the use of vasodilators in the therapy of migraine. In a small series at the New York Hospital, these drugs have proved effective in ending the vasoconstrictor stage and sometimes effective, though unpredictable, in aborting the later painful vasodilator stage. Carbon dioxide, the most potent intracranial vasodilator, will abolish scotomas, and sometimes abort early headache. It is given by face mask in a mixture of 10 per cent carbon dioxide and 90 per cent oxygen for three periods of four minutes each, with intervals of five minutes between each period. Four minutes at a time is about the limit of tolerance of the average person for the decided hyperventilation produced by this drug. In a few patients headache has been aborted during the prodromal stage by inhalation of amyl nitrite or by nicotinic acid orally in flushing doses of 100 to 200 mg. Once the headache is established, no therapeutic effect is obtained from this group.

A wide variety of other agents and procedures have been used and found moderately effective in the prevention of attacks. Comprehension of the nature of the migraine phenomena aids in the understanding of how such diversified, often irrational and sometimes frankly contradictory methods can modify the course of this syndrome. The importance of the patient–physician relationship cannot be overemphasized. Conspicuous among the factors contributing to the apparent effectiveness of many of these procedures are belief in the physician and the establishment of a clearly defined regimen.

Thus far measures for the management of the individual attack have been considered. However, it must be borne in mind that migraine occurs in a setting of life situations and attitudes which result in accumulated emotional tension and fatigue. Therefore, more important in the treatment of such a patient is the identification of the stressful factors in his life which lead to the phenomena of this attack.

## FACTORS LEADING TO MIGRAINE

First, it is essential to help the patient see the setting in which the attacks occur. Second, he must be aware of those personality features and habits which make him react as he does and thus predispose to the pernicious feeling state which leads to headache. Third, he must be brought to the realization that he must ultimately solve the problem in terms of his own equipment and experience, perhaps with the advice and support of his physician.

---

Read before the Section on Internal Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

From the New York Hospital and the Departments of Medicine (Neurology) and Psychiatry, Cornell University Medical College, New York.

Persons with migraine are not necessarily "neurotic" in the usual sense and, in fact, may have made a very successful adjustment in life. However, they have certain personality characteristics in common. They have the defects of their qualities.

They are tense, driving persons who are rigid, ambitious and perfectionistic. They have found that doing "more than and better than" their fellows brings a good deal of satisfaction. However, this end is accomplished at great cost in energy.

Considered reliable, conscientious and hard working, they find more and more responsibility coming their way. To this is added more stress by the belief that no one can do a job quite as efficiently or as thoroughly as they. Almost invariably persons with migraine delegate responsibility poorly.

They become resentful because they cannot keep up with the load which the world and they themselves impose. The natural outcome is tension, fatigue and exhaustion. In this setting, headache makes its appearance.

## MANAGEMENT OF PATIENT

The first step is to identify the personality features which make the patient liable to get into such situations and to visualize the stressful circumstances that bring him to the point where his body makes the insistent and painful demand to stop, which we recognize as the migraine attack. This is accomplished in an interview which uncovers, not only the usual medical data, but information as to the patient's background, his goals and standards and how he seeks and sets them.

Once the salient facts of the personality and the way of life are established in the mind of the physician, efforts must be begun to bring this understanding to the patient. Fortunately, because these persons are intelligent and aggressive, they will do much to work out their own problems when properly oriented and advised. Because of their fundamental insecurity and rigidity, many tend to deny that their "feelings" have anything to do with their headaches. This is where the physician can make each headache "pay its way" in terms of increased understanding by the patient of the events, emotional as well as external, which lead to his headache. It is important to realize that the period of twenty-four hours or so following a stressful period is as vulnerable as the period of tension as a time for headache to appear. The so-called "Sunday headache" is an example of difficulty arising in the "let down period" after a week of intense and exhausting application. Rage, resentment and frustration are often common denominators of the emotional derangement preceding an attack of migraine. However, dramatic events need not precede headache—many follow long periods of so-called routine living with slowly accumulating tension.

When allowed to discuss these matters freely, patients will frequently see a repetition of these pernicious emotional states in relation to other headaches.

Paralleling efforts to help the patient see the setting of the attacks and to recognize the relevant feeling states, there should be modification of his daily program. The amount of work which the patient is allowed to do should be reduced to three quarters of what he is "used to." This will relieve him of pressure and tension produced by rigid adherence to self-imposed quotas. He must be made aware of his fluctuating energy levels and urged to fit his work load as nearly as possible to his available energy.

Rest and relaxation are an integral part of the management of such a patient. Exercise commensurate with interests and capabilities, carried to the point of pleasant fatigue, not exhaustion, should be part of each day's program. Hobbies, especially those stressing motor activity, are to be encouraged.

At least eight hours of sleep at night and a mid day rest period must be assured for these persons who are inclined to dismiss sleep as a needless hindrance. Mild sedation with barbituric acid derivatives may be employed early in the treatment to facilitate the patient's change of pace. The sedative tub bath—warm, not hot—is advised for half an hour late in the afternoon and before bedtime as a regular routine.

Both the physician and the patient must be constantly aware that these chemical and physical measures to aid in relaxation as well as any drug therapy directed at the individual headache attacks are no more than crutches to help the patient into more efficient and less costly ways of living . A fundamental error in the management of migraine is to become preoccupied with the trees to the exclusion of the woods.

The patient must be urged to plan less for each eventuality and to allow himself to deal with problems as they arise, not before. He will need strong assurance of his ability to do this at first, but he will find, as he explores this new approach, that he is well equipped to deal with problems in this way. With greater spontaneity will come less anxiety and tension, which will in turn enhance his efficiency and productiveness.

The need for reassurance is repeatedly evident in these persons, emphasizing their true feelings of insecurity, which are frequently masked by a sophisticated, self-assured manner. They are beset by grave doubts in many spheres, and these anxieties add to their tension and thus contribute to their illness. An important part of the treatment is to afford them ample opportunity to discuss whatever problems they feel are pressing, regardless of the apparent relevance to the problem of headache. The attention and support of a sympathetic and understanding physician who discusses and informs but does not judge is a major therapeutic agent. During the reorientation and readjustment that patients with migraine must necessarily make, this reassurance and support must be constant and unvarying. If the patient who is making what for him are major fundamental changes in his way of life feels for a moment that the physician is uninterested or unsympathetic he will abandon all that he has gained and return with greater tenacity to his former habits.

This approach to the problem of migraine has been used at the New York Hospital for the past fifteen years. It has been used by many physicians of varying degrees of experience under a variety of circumstances.

In evaluating this form of therapy one must realize that it may demand more in terms of personal adjustment than the patient may be willing to make. Many persons are satisfied to learn that they do not have a brain tumor and are unwilling to pursue the matter further. It is the physician's responsibility to make the patient aware of the cost of his way of life and then to support whatever decision the patient makes as to what he wishes to do about it.

In 1940 Wolff made a detailed study of 64 patients with migraine who were treated by this method. Sixty-four per cent had no headache or less frequent and less intense attacks; 16 per cent still had headache which was controlled to some extent, while 20 per cent had failed to improve. A random selection of 50 cases seen by various physicians in our clinic within the past three years showed a similar result. Approximately two thirds of the patients were free or nearly free of headache, while the remainder were not benefited.

The development of less costly ways of life, analysis of the special circumstances under which individual attacks may occur and information of the specific changes necessary are the primary goals of successful therapy in migraine. Many persons who have been successful to a degree while carrying on under their largely self-imposed stresses are fearful and doubtful about changing their way of life for another which appears "inefficient" and perhaps formless. It means to them replacing a tried and reasonably effective way of dealing with life situations with something which seems entirely opposed to everything that they have ever done. It is essential that they realize that, in fact, to allow themselves more spontaneity and freedom of action, it is to bring into use a part of their personalities neglected or unrecognized.

## SUMMARY

Therapy of migraine falls into two categories: treatment of the attack and prevention of recurrences.

Many of the preheadache phenomena are associated with intracranial vasoconstriction. Intracranial vasodilators abolish these initial symptoms and may sometimes but unpredictably abort the headache. The headache is associated with painful vasodilatation of cranial arteries. Ergotamine tartrate parenterally is the drug of choice for the management of this stage and is most successful when administered at the onset of the headache.

Emotional reactions and attitudes that result in accumulated tension and fatigue set off a series of bodily changes which result in the migraine attack. Reduction in frequency and severity of attacks depends on identification and modification of stressful factor in the relationship of the patient to his environment. The physician must guide the patient into less costly behavior patterns and lend emotional support during this reorientation. About 2 persons out of 3 can be helped, in terms of reduction in frequency and severity of headache, by such reorientation.

---

## ABSTRACT OF DISCUSSION

Dr. Roland P. Mackay, Chicago: I believe the division of the treatment of migraine into the treatment of individual attacks and the prevention of attacks is sound and wise. One must not pay too much attention to the individual attacks, but must think also of their prevention. In this regard, psychologic aspects are important although they are not the only ones to be considered. For me, it is helpful to try to formulate a picture of the personality structure of these patients. A remarkable number of persons with migraine are alike mentally, and Dr. Marcussen has presented to you those characteristics with great fidelity to the facts. Usually these patients are intelligent, keenly perceptive, thoroughly controlled persons, who often have a sense of inadequacy and an inner urge to overcome this inadequacy. They want to be accepted. Consequently, they are intolerant of obstruction both by persons and by things. They are "the finest people on earth," if I may use that expression. They keep the wheels moving. They often exhaust their energies, but are usually able to keep on going and finally pay the penalty. They are responsible for much progress, but are somewhat perfectionistic. Since they are so well controlled, they find themselves often inhibiting or suppressing their own hostilities. It is this repressed hostility that is so frequently the precipitating factor in inducing attacks. The inherited element in migraine seems to be a physiologic mechanism which is potentially ready and which the psychologic and other precipitating factors set in motion. I believe that the prevention of attacks must start in childhood. If parents start with a child, accepting him with abundant love and admiration, emancipating him early and putting him on his own responsibility, he will not likely grow up to suffer from migraine of psychologic origin. In my experience 10 mg. of ergotamine tartrate by the mouth is too much, and probably would lead to undesirable individual reactions. Dihydroergotamine is at least as effective as ergotamine tartrate and much less apt to be toxic. I believe it is worthy of supplanting ergotamine tartrate entirely.

Dr. Eugene Foldes, New York: I suggested that in migraine intracranial retention of liquid and consecutive irritation of certain structures of the brain is important. This concept led to the therapeutic application of the dietary which I called antiretentional. The antiretentional diet is high in proteins and vitamins which have an antiretentional action and is restricted to a greater or smaller extent in carbohydrates, fats, liquids and sodium chloride, which are conducive to retention of liquid. The efficacy of this treatment in the prevention of migraine was confirmed. In several publications during the last fifteen years I proposed that for the development of certain diseases such as migraine, epilepsy, the eclampsias, Ménière's syndrome, gout and bronchial asthma two factors are necessary. The one is a disturbance in the general water and mineral metabolism and the other factor is a local predisposition for temporary accumulation of liquid in one organ or another. I suggested that the local predisposition is a result of local circulatory disturbances. We may identify vasoconstriction and vasodilatation, emphasized by Dr. Wolff and others, as the local circulatory disturbances in the brain which, in the presence of disturbed general liquid metabolism, lead to temporary edema and the attack of migraine. Certain therapeutic measures are based on the concept that vasomotor disturbances are instrumental in migraine. These therapeutic measures are successful in terminating the attack once it has developed. In contrast, the aim of the antiretentional therapy is the prevention of migraine by preventing intracranial accumulation of liquid. If we succeed in this aim, vasomotor disturbances either do not develop or else are ineffective in producing the migraine paroxysm. This is demonstrated by cases of my observation in which ergotamine preparations were used by patients regularly before the institution of antiretentional therapy. Subsequently the administration of these preparations could be discontinued because no more attacks of migraine developed.

Dr. Robert M. Marcussen, New York: I agree with Dr. Mackay's statement that 10 mg. of ergotamine tartrate by mouth is a large dose. We advised that amount because we think that is the maximum that can be taken; if no effect is obtained from 10 mg. taken in an hour and a half, it is unlikely that oral medication will be of any effect in that particular attack. The oral administration of ergotamine tartrate is at best much more unpredictable than parenteral administration. A wide variation in the tolerance of individual persons for ergotamine tartrate has been observed. We have always emphasized that it should not be given orally or parenterally more than once a week. However, we have 2 patients, one who has taken ergotamine tartrate hypodermically daily for nine years and another one for fourteen years with minimum side effects. They represent extremes but suggest that ergotamine may be better tolerated than has been thought in the past.

# ULCERATIVE COLITIS

## Ileostomy: Problem or Solution?

LELAND S. McKITTRICK, M.D.
and
FRANCIS D. MOORE, M.D.
Boston

Idiopathic ulcerative colitis lends itself particularly well to discussion before a combined meeting such as this. Its problems present a real challenge to internist and surgeon, for only through the understanding and well coordinated efforts of both can the patient be assured of a quality of care likely to succeed.

It is not our purpose today to outline details of clinical diagnosis or technical management; we wish instead to emphasize the principles followed in surgical care and the indications for the several operations used. From a study of the postoperative results in the group of patients who have been under our personal care and under the care of those associated with us in this assignment at the Massachusetts General Hospital,[1] we have attempted to determine just what adjustment the patient with an ileostomy can make to the social and economic problems presented to him. At the present time, there is widespread interest in methods of therapy, surgical or otherwise, which avoid ileostomy or substitute for it other defunctioning procedures. As a preliminary to understanding such measures or the need for them, we must come to a realistic evaluation—from the patient's point of view—of the nature of social existence with an ileostomy.

### THE PATIENT

Much has been written in recent years concerning the psychiatric aspect of ulcerative colitis, and much emphasis has been placed on the importance of the psychiatrist in the treatment of the disease.

As surgeons, our more intimate contacts are with those patients who, for one reason or another, have not responded to medical treatment. We recognize fully the emotional instability of most of them, but we emphasize the seriousness of the organic disease and insist that responsibility for these patients should remain with the internist or surgeon and not be transferred to the shoulders of the psychiatrist.

An occasional patient with the disease is eminently "treatable" psychiatrically; such patients may or may not exhibit the "grief response" considered to be of specific significance by Lindemann. More frequently, organic disarrangement proceeds *pari passu* with mental disorder in a fashion which renders classical psychiatric technics difficult and dangerous.

Of greater significance in a general sense has been the realization that the ulcerative colitis patient is a strongly dependent personality and that a filial devotion to physician or surgeon may develop during treatment. The psychiatrist has clarified this fact and brought it into sharp focus by his frequent demonstration that the patient with ulcerative colitis has lost a parent, sibling, friend or mate on whom he formerly was dependent, an event immediately preceding onset of symptoms. This sets the stage for a physician-patient relationship of extraordinary importance in the surgical care of the disease.

Of greatest importance is the recognition by the internist and surgeon of the value of this close physician-patient relationship. This is particularly true following ileostomy, when the patient seeks an emotional attachment to someone who understands his physical and emotional problems. Recognition and acceptance of this responsibility by the surgeon permit the patient to develop dependence and afford him the relationship so essential to complete adjustment. The surgeon will rarely be called on to be a more effective psychiatrist than in dealing with this complex disease, and he will see few patients who are so appreciative of understanding, interest and encouragement.

### PRINCIPLES OF TREATMENT

Many patients respond well to careful and understanding medical care; it is the patients with intractable disease who must be cured by surgery. With but few exceptions the price paid for eradication of the disease is a permanent ileostomy.

What should be our objectives in the management of a given case? Should we be content to offer the patient a life of reasonable comfort and semi-invalidism with his gastrointestinal tract in continuity or should we seek more, possibly a complete cure, or at least control at a level which permits normal development of the child and a productive, useful life for the adult? Is ileostomy too much to pay for a cure? What is the place of the patient with an ileostomy in the social and economic life or his or her family and community? The answers to these questions are of primary importance in the understanding and management of patients with this condition.

*Objective of Surgical Treatment and Responsibility of the Surgeon.*—It is our objective in the management of the patient with ulcerative colitis to return that patient to society capable of becoming a useful member of his family and community life.

Any form of surgical treatment which does not have an ileostomy as its initial step is so unusual that it is of little statistical significance in a general discussion of this type. Despite the widespread impression that early ileostomy will result in control of the pathologic condition of the colon and permit later closure in a high percentage of cases, we know of no convincing evidence to support this. It is our belief that ileostomy in the very early stages of the disease will not permit later closure (with permanent arrest of the disease) in enough patients to warrant its routine performance. Essential to a happy life with a permanent ileostomy is a patient who has known the ravages of the disease and who prefers the inconvenience of an ileostomy to existence with partially controlled colonic symptoms. If routine ileostomies are performed on patients who have not experienced the full impact of the disease, many will find it impossible to adjust themselves satisfactorily to their ileostomies.

The responsibilities of the surgeon are great. Once ileostomy has been recommended as the procedure of choice, he must be prepared to give untiringly of his time and thought to the many details in the postoperative care of the patient. He must accept the responsibility of restoring that patient to a state of good

From the Surgical Services of the Massachusetts General Hospital, Boston.

Dr. Andre Monsaingeon, of Paris, France, made the tabulation of material from the records of these patients.

Read before the joint meeting of the Section on Gastro-Enterology and Proctology and the Section on Surgery, General and Abdominal, at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

[1] Drs. R. H. Miller, Boston; John Stewart, Buffalo; Champ Lyons, New Orleans, and Richard Warren, Boston.

health and be prepared to advise and carry out whatever additional surgical treatment is necessary to accomplish this end; *in addition, he and the internist must* assume responsibility for aiding the patient in the readjustment necessary to a productive and happy life.

### INDICATIONS FOR OPERATION

*A. Ileostomy.*—There is no decision in surgery which may be more difficult to make than the decision for or against the performance of an ileostomy for a patient with ulcerative colitis. *Before advising this operation,* proper consideration should be given to the psychologic as well as to the medical indications. If the operation is to be successful, not only must the disease be controlled, but the patient with that disease must be satisfied and grateful for the health which has been regained. It is our firm belief that until the patient recognizes need for the help which ileostomy offers and unless he has a real incentive to live and to overcome this new handicap, ileostomy may be inadvisable even though the medical indications seem clear.

We may roughly divide the indications for ileostomy into three groups as follows:

1. Life Saving: This group includes those patients with an acute exacerbation (or with an acute fulminating disease) *in whom medical treatment has failed* to bring about a remission. Perforation of the colon is not an unusual complication in the more acute form of the disease and is an indication for immediate ileostomy. It is possible that with streptomycin and other agents an occasional life may be saved by prompt diversion of the fecal stream and intensive antibacterial therapy. The real difficulty comes in determining whether or not medical treatment has failed, in the cases of less acute disease. For a patient who under ideal hospital conditions has received thorough medical treatment to combat existing infection, anemia and nutritional disturbances and who has failed to respond to such treatment, ileostomy *may prove a life-saving* procedure. If this is postponed beyond a reasonable period, irreversible changes or perforation may take place and the opportunity for a successful result following ileostomy will have passed. The surgeon should be asked to see these ill patients in anticipation of later surgical treatment in order that he may follow the progress of the patient and better judge the time at which ileostomy, *if necessary, shall be done.* We have found it helpful in the management of our cases to make a definite deadline for such medical management. At the end of a specific period, be it one week, two weeks, longer or shorter, the entire problem is reviewed and a decision made for or against operation; if operation is postponed, another period is laid down, at the end of which the entire problem must be reevaluated. Only in this way has it been possible for us to avoid indefinite postponement of an indicated procedure.

Recurrent massive hemorrhage is one of the most serious of the complications of this disease. It is always a grave occurrence, and, if the hemorrhage is massive and recurrent, it is of great importance that ileostomy not be postponed too long. Moreover, it is our experience that ileostomy alone will only rarely result in the control of this hemorrhage. We have found it necessary to proceed with extirpation of the bowel to control the hemorrhage. The mortality in this group of patients will, of necessity, be high, but, by aggressive action not too long postponed, an occasional life will be saved, which on more conservative treatment would have been lost.

2. Polyposis: The development of multiple pseudopolyps or true adenomatous polyps is in our judgment an indication for a graded operation, consisting of ileostomy and later colectomy to prevent the development of cancer.

3. Intractable Chronic Disease: The patient who is chronically ill with the disease, a semi-invalid although ambulatory, and unable to carry on with the normal activities for one of his or her age, has not had a satisfactory response to medical treatment. Ileostomy, followed by colectomy if necessary, will usually restore such a patient to a normal state of social usefulness. Also classed as unsatisfactory are the results following medical treatment of those patients who, in spite of good care, continue to have recurring acute or subacute exacerbations, requiring frequent hospital admissions; these patients are neither physically nor economically secure and should not be regarded by the internist as in a state of satisfactory control.

Postoperatively, the patient will usually follow one of four courses. He may have a remission of indefinite length and for all practical purposes may be considered to have had a complete symptomatic cure, or the response to ileostomy may seem initially satisfactory, but at some later time there is a reactivation of the disease in the colon. There will be a third group of a relatively few patients who derive inadequate benefit from ileostomy; they are improved, but do not fully regain their normal weight and strength. Finally, there is a small group of patients who show no apparent benefit following ileostomy. This group includes certain of those with the acute fulminating type of disease which goes on to a rapidly fatal outcome and the patients with massive hemorrhage for whom further aggressive surgery is essential.

*B. Colectomy.*—The indications for colectomy are not difficult to determine if one accepts as the objective of surgical treatment the complete physiologic or anatomic elimination of the disease. If this is not accomplished by ileostomy alone, further surgical treatment is essential. The indications may well be grouped under the following headings:

1. Polyposis: Because of the increased incidence of carcinoma in patients with chronic ulcerative colitis and because of the fact that polyposis is a particular predisposing factor, we believe that such a patient should have removal of the diseased colon. As in so many of the phases of colitis, the conservative measure is the aggressive one here. In several instances suspect colons removed as cancer prophylaxis have proved to have established carcinoma; with ileostomy the patient cannot exhibit the early symptomatic manifestations of cancer of the colon and roentgen examination is often painful and unsatisfactory for detailed interpretation.

2. As a Life-Saving Procedure: Recurrent massive hemorrhage which does not stop after ileostomy may require early removal of the colon and the rectum. Occasionally ileostomy fails to precipitate a remission in the acute form of the disease, or an acute exacerbation of the disease following ileostomy will not respond to medical measures, and removal of the colon is necessary in an effort to prevent death from continued activity of the disease in the colon.

3. Unsatisfactory Response to Ileostomy: In those patients whose response to ileostomy has been less than completely satisfactory and in whom careful studies fail to show any other cause for failure to gain satisfactorily in weight and strength, the disease in the colon may be considered to be the limiting factor, and for these patients colectomy is indicated.

4. Reactivation of the Disease in the Colon: One exacerbation of the disease in the colon following ileostomy is a positive indication for colectomy. In our earlier experience, we allowed a patient at least two recurrences before advising the removal of the colon. Because of the seriousness of an acute exacerbation after ileostomy and because on one or two occasions the desire to postpone colectomy nearly cost the life of the patient, we have now come to feel that a single exacerbation is a positive indication for an elective colectomy. It should be done during the same hospital admission for which the patient has been treated for the recurrence.

5. Miscellaneous: There are several other indications for colectomy. A few patients with chronic secondary anemia which would not respond to iron or to other treatment have been restored to health by removal of the diseased colon. Chronic infections of the skin which have failed to respond to treatment have healed promptly when the diseased colon has been taken out. We have also advised colectomy in a few patients with a second chronic disease for which there was no specific treatment, such as minimal lesions of pulmonary tuberculosis and, more particularly, rheumatoid arthritis. Some, but not all, of the latter group have been markedly helped by the elimination of the diseased bowel.

*C. Proctectomy.*—It is not our policy to remove the rectum as a routine procedure. If a specific treatment for this disease becomes available, a few of our patients may ultimately have an anastomosis between the terminal ileum and a functioning rectum. For this reason, the lower segment of bowel is maintained unless there is some definite indication for its removal. The indications for the removal of this segment of bowel are not difficult. Polyposis is a definite indication. Activity in this segment of bowel which persists or recurs after the colon has been eliminated is also an indication for its removal. Finally, local sepsis around the perianal area originating in this bowel can be eliminated only if the involved bowel is removed.

## HOSPITAL STATISTICS

Within the scope of this study, 149 patients with ulcerative colitis have had an ileostomy as the initial (or only) procedure in an attempt to control or cure the disease. Twenty-two, or 14.8 per cent, died after operation. The majority of these deaths have resulted from unchecked advance of the disease as manifested by perforation or hemorrhage, or both, in the early postileostomy period. They do not represent death from ileostomy per se but, instead, mortality from ulcerative colitis beyond help from ileostomy.

Eighty-seven, or 68.5 per cent, of the survivors of ileostomy have had a subtotal colectomy at intervals varying from months to twelve years after the ileostomy. The mortality was 6.9 per cent. Thirty-three or 40.7 per cent of those surviving colectomy have had removal of the rectal stump by the combined abdominoperineal route with a mortality of 3.3 per cent (the table).

Only 5 patients have had gastrointestinal continuity reestablished. Three of these failed to respond favorably. Two who had a second ileostomy are now in excellent condition at this time, and the third, who nearly died of an acute exacerbation of the colitis immediately after closure, remained a chronic invalid from the disease and recently died following operation for a brain tumor. One patient, whose colectomy was done in 1939, had an anastomosis between the terminal ileum and rectal stump seven years later and has remained well for two years. Another had a subtotal colectomy and ileosigmoidostomy one year ago, five years after the ileostomy. Although in good health, this patient feels that he was better with the ileostomy than since he has been reconnected.

The many problems which have arisen in the hospital care of these patients will not be discussed in this paper. The care of the ileostomy, the problems of fluid balance and nutrition and subsequent operations for the disease or for the complications of previous surgical treatment (especially prolapse or stenosis of ileostomy and intestinal obstructions) place heavy obligation on the surgeon and challenge his skill in the art as well as the science of surgery.

*Ulcerative Colitis, Massachusetts General Hospital, 1932-1947*

| Operation | No. of Cases | Deaths | Mortality, Percentage |
|---|---|---|---|
| No operation | 229 | 12 | 5.0 |
| Ileostomy | 143 | 25 | 17.4 |
| Subtotal colectomy | 87 | 7 | 8.0 |
| Proctectomy | 33 | 1 | 3.3 |
| Restitution of continuity | 5 | 0 | 0.0 |
| Total cases | 372 | 45 | 12 |

## LATE RESULTS

Complete elimination of the symptoms of a nonmalignant disease such as ulcerative colitis would be an empty victory were the patient not restored to a position of comfort, usefulness and ability to enjoy most of the satisfactions and pleasures of life. To most of us who enjoy good health, ileostomy means a life of social ostracism and economic dependence. "I would rather be dead than have an ileostomy," is a statement not uncommonly heard. Does one hear such statements from the patients themselves, or are they adjusted to the inconvenience of the ileostomy, philosophically accepting it as a solution to the crippling disease from which they formerly suffered? We have sought the answer to these and related questions by submitting a questionnaire to each patient which left him considerable latitude for an expression of opinion.

Questionnaires were sent to one hundred and ten patients who have left the hospital with an ileostomy.

We have had replies from all patients or their families. Five have died natural deaths from other diseases. One died two days after an overdose of a barbiturate.[2] Of the 104 patients whose present condition is known, 50 are males and 54 are females.

*General.*—Eighty-eight or 84 per cent of these patients consider themselves to be in good health at the present time. Of the remaining 16 patients, 4 are crippled by other conditions; 3 undoubtedly have active disease in the colon or some abnormality of the stoma which should be corrected surgically. Of the 9 who have not become adjusted to their ileostomies, it is probable that 5 may be greatly helped by a change in appliance or ileostomy outlet. In interpretation of these data, it is of importance to realize that this classification is based on the opinion of the patient and is, therefore, a composite of emotional as well as the physical factors.

---

[2] This was officially reported by the medical examiner as accidental death.

*Economic Status.*—Ninety-seven per cent of the 104 patients are working as housewives, are in schools or are gainfully employed. There is a wide variation in the types of occupation—mill workers, truck drivers, a college professor, school teachers, dentists, physicians, medical secretaries, salesgirls, etc., with a tendency to avoid heavy labor for fear of injury to the ileostomy or of displacing the apparatus. Seventy-five per cent feel that their earning or working capacity is not lessened by the ileostomy.

*Social Activities.*—Sixty-seven per cent feel that their social life is satisfactory and not adversely affected by ileostomy. Of the 32 patients who feel that there are limitations, 13 referred particularly to problems arising when spending the night with friends or going on camping trips, or to activities where lack of facilities or too intimate contact with others prevented proper attention to the ileostomy. There is a surprising freedom on the part of these patients to enjoy most of the common activities, including athletics.

*Marital Status.*—Seventy of the patients are married; 34 are single. Twenty-three have married subsequent to the operation, and 1 more of the young women is to be married in the near future. Five have gone through one or more pregnancies subsequent to ileostomy. An understanding husband or wife and the satisfaction and responsibilities of children are undoubtedly important stabilizing factors in the lives of these patients.

### ILEOSTOMY PROBLEMS AS SEEN BY THE PATIENT

The results of a study such as this are dependent on the total response of the patients to the treatment given. It would seem fitting, therefore, that some of the text be written by the patients themselves.

*Readiness to Accept Ileostomy.*—We have previously referred to the importance of the psychologic as well as the physical indications for ileostomy and have suggested that the patient who has really known the handicap of the disease is in the best position to be grateful for ileostomy and would, therefore, adjust more readily to it.

M. W. was 21 years of age when ileostomy was performed. Two years later, a subtotal colectomy was necessary because of recurrent activity. At the present time her life is "happier and more complete than it has ever been. None except a colitis sufferer will ever know the terrible insecurity that goes with the inability to control movements and the awful all-gone feeling that is the result of loss of appetite and accompanying anemia. These I had for years (about ten) and can trace the present ideal situation only to the alleviation of the colitis through the ileostomy." She is now 28 years old, working as receptionist for a publisher, and evenings enjoys the usual social activities for one of her age.

E. M. writes: "Like all people, I fought off an operation as long as possible. When it became necessary after eight years of colitis, I accepted it with the feeling that my usefulness was over. But I have found quite the opposite to be true. When I look back on the years that I dragged around with colitis, I realize that I am the luckiest person to be able to live a completely normal life again and I wish I had had the operation long before I did."

The tale of R. G. epitomizes some of the reasons these patients have for gratitude: "Mine was a tough case of colitis. I could not go anywhere or do much of anything. There was not much control of the colon. I did not dare go to a show, or any outside entertainment or visit anyone. If I went in my auto, I had to take a bed pan along. The year I went to Florida, I went riding and driving through most of the big cities sitting on a bedpan. The ileostomy has changed all this. I do most anything I want to now. . . ." The patient goes on to state that he is still somewhat bothered by arthritis; he should be surveyed for the possibility of further colonic removal with this in view.

Adjustment is not so easy for one taken acutely ill, whose medical past is one of good health. To this group, particularly, there must be some real incentive which makes life worth while even with a handicap. Mrs. I. S. was 38 years old when she was taken acutely ill after childbirth. She did not respond to medical treatment, and ileostomy was done as a life-saving procedure. She had a dramatic response, became completely well and remained so for twelve years (1947), when an acute exacerbation of the disease occurred. Again it resisted all treatment. Subtotal colectomy was carried out while she was acutely ill. To her "the whole idea of living with an ileostomy was terribly repulsive," but she has been "most grateful that this operation was performed, for it has enabled me to bring up our three children and share in their activities as well as to share my husband's interests. At the time of my illness in 1932, the children were only 7, 4 and 1 month old. Their need of me was a powerful incentive to live and make the best of things. Even that incentive would not have been helpful if it had not been for unfailing cheerfulness and encouragement of my husband—not all patients are so fortunate, and I am not sure what my reaction would have been in other circumstances."

*Adjustment to the New Mode of Life.*—Regardless of the relief from invalidism or incentive to get well, adjustment to the altered way of life is not easy. Many patients, in writing, stress the encouragement and help that come from early interviews with patients who are well adjusted. The importance of confidence in one's self, and encouragement from those who know, are well brought out by one of our patients (J. L.), a young dentist who had an ileostomy performed four years ago at the age of 25. "I feel that once the mental shock which goes hand in hand with the first realization that you have an ileostomy has been overcome, the rest is comparatively simple. I know as far as I was concerned, my mental attitude toward the whole business was one of utter defeat and visions of loss of everything I held precious as far as having a family, getting married, engaging in sports, etc. However, after gradually getting used to the ileostomy (mentally, that is), I realized that I was not handicapped as far as these things were concerned. At first, I feared everybody could see I had an ileostomy. This was dispelled when I mingled with crowds and heard no comments. Secondly, I feared getting married because I would not be able to perform my marital duties; this was wrong. Then I felt I could not run my practice as a dentist; this was wrong. I found that in every instance, once I had overcome the idea of having had an ileostomy, I could undertake all that I could before." He then stresses the help that would come from a visit before leaving the hospital by "another ileostomy patient who has successfully climbed all of the hurdles."

W. S., an attractive young woman of 23, who has had her ileostomy eight years, writes, "I am at present leading a completely normal life but it has been a fight in my case with a lot of trouble and and heartbreaking experiences. I'm a successful model now. . . . but there is still in the back of my mind the wish that I could be connected up again—and that perhaps some day a different cure, one not so ugly and hard to take will be found."

M. H., a university professor, writes: "I have lived with my ileostomy for fourteen years already and have had a full, active, and happy life. I do not mean to infer that living with an ileostomy is as good an arrangement as nature provides. All I want to say is that one can manage very successfully with one. I have traveled everywhere with my ileostomy. . . . It has enabled me to do creative, constructive work and to bring up a fine family. . . ."

A. P. writes: "Put me down as the A-1 ne plus ultra, super duper fan of ileostomy. . . . I am unbelievably better fitted to engage in any activity, mental or physical, than I was during the years I had colitis."

Unsatisfactory adjustments have occurred in 10 of our patients for a wide variety of reasons. The appliance itself may be a source of difficulty. The skin-cement type of bag in rare cases fails to give satisfaction. R. S. writes: "The whole thing is a mess, whatever I do. If it could only be regulated! I just can't stay on a diet, I love all kinds of food. . . I tried the new bag, cementing it on, but my skin couldn't stand the cement, it was too irritating." In the future, this patient should be encouraged to maintain herself on a more rigid diet despite her omnivorous tendencies; experimentation with various types of skin cement is also in order.

The most unsatisfactory adjustment is apt to be found in the uneducated man, of low native intelligence and ingenuity, especially if his work is heavy outdoor work not easily interrupted for maintenance of ileostomy hygiene. H. G., a farmer and lumberman, writes: "I cannot do everything that the rest of the crowd does. . . . soon get the name of a poor sport. . . . I don't believe anyone can have an operation like this and still lead a normal life. If I had to do it again in the same circumstances . . . I would never have an operation like this." Despite his handicap, the patient was married after ileostomy and has fathered 6 children in rapid succession.

*Marital and Sexual Problems.*—Sex problems are of a peculiarly complex type with ileostomy; they may be further complicated by proctectomy.

In the male, problems center themselves around the question of social acceptability for sexual contacts and intercourse; and, in addition, the physiologic possibility of impotence resulting from pelvic nerve interruption in proctectomy. In the female, social acceptability for sexual contacts and intercourse is also a problem; and, in addition, obstetric problems arise incident to ileostomy and to the reconstructed pelvic floor following proctectomy.

In the case of most of the married men, the wife has been an understanding partner and the relationship has not been altered.

W. C., for instance, writes: "My wife thinks nothing of it, and it hasn't changed her actions towards me one bit."

One wife writes: "Our sexual relations are better than they were before the ileostomy because of the colitis condition," pointing up the fact that the untreated disease is hardly one to encourage normal sexual activity. She continues: "It took me many months to get used to this and before I could bring myself to having marital relations again. I feel that if something other than a pouch were invented for use during coitus, a marriage could be happier. . . . something should be made that is flat instead of a bag." This couple could be made more comfortable by education in use of the newer ileostomy appliances.

For unmarried men the problem of "telling the girl friend" has not been an easy one, but has been surmounted in most cases, often with the help of the surgeon or internist, and a fruitful marriage has followed.

C. A. was married despite ileostomy and colectomy and has fathered 3 children; the sexual act is quite normal.[3]

For the unmarried girl, the problem of informing a prospective mate of the true state of affairs seems almost unsurmountable in occasional instances. Feelings of pride are in conflict with the humiliation of revealing an ileostomy to the prospective mate.

Patient N. H. illustrates some of the aspects of failure in sexual adjustment. A slightly built girl with little native drive and ambition, she has several times encouraged men of her acquaintance, only to break off social relations when intimacy threatened revelation of her ileostomy. She not infrequently weeps in discussing these matters, and will not accept the solution of making a clear understanding with her "boy friend" despite the knowledge that others have done so. This conflict persists. She writes that her friends do not know of her handicap . . . "I keep it to myself and do not like to have anyone know . . . Marriage is a hard life to lead with an operation like this. So far I have no intention of marriage at all."

Another girl, R. S., has similar feelings. . . . "I would like to get married, but I have a fear of being turned down. . . . especially if he should know I cannot bear him children. . . . if I went out and someone wanted to be affectionate, I am afraid."

In the case of patient D. L., a different variation is found. A Jewish girl of intelligence, insight and attractive personal appearance, she avoids social contacts which might lead to engagement or physical intimacy because of a deep conviction that she should not "foist herself" on a husband, even though he were willing, "any man deserves a normal wife. . . . why should he have me?" expresses her reaction. She writes, "Speaking for myself, truthfully, it's a curse! My ileostomy is inclined to be runny, and when it's in good working order, I am very aware of odors."

---

[3] In performing proctectomy by the combined abdominoperineal route in these cases, considerable care has been exercised to keep the dissection close to the bowel and to avoid undue nerve injury. At this writing, we are not aware of impotence in young males from this procedure, although we recognize its occurrence following the more complete dissection for cancer.

Obstetric aspects of ileostomy have not been fully explored. If the colon is quiescent and the patient has adequate insight into the problem presented, pregnancy can be carried to term and pelvic delivery effected.

Mrs. D. C. has had two successful pelvic deliveries despite ileostomy and colectomy. In other instances, smoldering colonic activity often lighted up by pregnancy has been an indication for the termination of pregnancy or contraceptive advice.

The problem of the obstetric uterus after combined abdominoperineal proctectomy needs more clarification. Mrs. A. G., recently married and three months' pregnant with a much desired child, underwent abdominal hysterotomy to empty the uterus because of the suspicion that posterior fixation might lead to thinning of the anterior wall and the threat of rupture. At operation the uterus was found to be entirely free in its peritoneal surfaces; it is quite probable that satisfactory completion of pregnancy could have been carried out in this case, as it has in others after removal of the rectum for cancer. It is of interest that this patient (Mrs. A. G.) had not even met her future husband at the time of ileostomy, but by patience combined with intellectual fortitude overcame her hesitancy to tell him of it, secured his confidence and has been happily married.

Limitations of space do not permit more extensive quotations from comments of the patients; detailed analysis of their present status has provided the basis for the foregoing statistical analysis.

## CONCLUSION

Careful selection of the patients for ileostomy and of the time at which it is done, establishment of a satisfactory stoma, physiologic or anatomic elimination of the disease, the selection of a proper appliance and instruction in its use are responsibilities of the surgeon in dealing with ulcerative colitis. With this help and with aid and encouragement from patients who are well adjusted, the person so unfortunate as to require a permanent ileostomy may be assured the security of good general health and a respected place in the economic and social life of the family and community.

The satisfaction and socioeconomic rehabilitation produced by ileostomy are gratifying to patient and surgeon in 70 to 90 per cent of patients, depending on the criteria used. The most unsatisfactory life adjustment is made by the outdoor-working laborer (male) and by the unmarried woman who finds in ileostomy a barrier to the inception of sexual relations.

This fact should be taken into account when heroic methods of closing or avoiding ileostomy are under discussion. "Ileostomy is not the end of everything, but rather the beginning of a new life slightly altered." (J. L.)

## ABSTRACT OF DISCUSSION

Dr. Clarence Dennis, Minneapolis: The differences of expressed opinion are due to the fact that the etiologic factors underlying these diseases are unknown. We have seen cases in which sensitivities have played a dominant role, others in which dietary or traumatic factors dominated or in which some specific infection participated, and still others in which personality maladjustments have seemed most important. The medical and surgical therapy at the University of Minnesota has included each of these factors. In a twelve year survey it was found that 72 cases treated primarily conservatively suffered an initial mortality above 20 per cent. The corrected figures show half the group dead in five years, two thirds dead in ten and only 1 of the 8 known survivors at that time in satisfactory condition. Among the 41 treated surgically in this period, the initial mortality was 7.3 per cent, and 75 per cent were known to be alive at the end. Most successful was ileostomy followed by one stage colectomy. The surgical mortality of colectomy was zero, and 28 of the 30 patients are alive an average of four years afterward; of these, 22 are well and active. The 10 deaths in the 41 surgical cases were half due to cancer. Routine colectomy, therefore, should cut our over-all mortality in half. It has already twice removed subclinical unsuspected lesions. In 15 per cent of our five year cases cancer of the colon has developed. In another 15 per cent cirrhosis of the liver has developed. Two years ago, Dr. C. J. Watson suggested vagotomy in a patient suffering enteritis in the remaining 6 feet of small bowel. The response led to application in 30 cases. Three fourths of the patients are improved or entirely free of symptoms. The rationale rests on (1) relief of enteric spasm, (2) reduction of motility of the entire intestine, (3) the apparent blocking of the rectosigmoid response to emotional stress and (4) the observation of Lillehei and his associates that the fatal diarrhea seen in dogs after mesenteric ganglionectomy does not occur if the vagi are divided. A favorable response in the proctoscopic and roentgen appearance is seen in most of the cases within a few weeks. We do not know how to select the cases that will respond best and we do not know how long favorable effects will endure, or whether long term harmful effects will appear. The procedure, therefore, should be regarded as under scrutiny and not yet ready for general application.

Dr. Burrill B. Crohn, New York: Regional ileitis is the popular name assumed by most writers and thinkers; there is no question but what the whole small bowel may be involved. In the recent survey of my cases—about 300 cases of ileitis—260 of them involved locally the terminal ileum proximal to the ileocecal valve, 35 were of ileojejunitis and 22 cases were combined cases involving ileum and colon. That ileitis and colitis are essentially the same disease and belong more or less in the same family I feel has justification. These diseases are all diseases of young persons. That is one reason for believing that they have a common factor. Ileitis, jejunitis, appendicitis and ulcerative colitis are all diseases that occur essentially in young persons with driving personalities. The mixed forms of the disease again bring to mind the fact that these diseases may have a common factor. The more one sees of these mixed forms, such as involvement of terminal ileum and right side of the colon, or the terminal ileum and the descending colon or sigmoid, or terminal ileum and high jejunum, the more one is made aware of that fact. After resection for granulomatous disease, a recurrence may take place in either the small or the large intestine. In one family of 4 siblings, 1 had duodenal ulcer, one a segment right-sided colitis, 1 universal colitis and 1 regional ileitis. It may be possible that this is not initially a disease which is initiated by a psychic frustration or psychic trauma, but to treat or attempt to treat ulcerative colitis by psychoanalysis in the presence of a temperature of 103 F. and toxic manifestations and severe diarrhea is to waste one's time and to waste the patient's time and money. Once the conflagration has been started, once the intestine has become ulcerated, the time for the role of psychotherapy has long since passed. To attempt to treat that patient and not have a rapport with the patient, not to know whether the patient is sympathetic with you, leads frequently to frustration. To cure ulcerative colitis one must be in perfect sympathy, psychic sympathy with the patient.

Dr. Lester R. Dragstedt, Chicago: Dr. McKittrick has given us a thoughtful and adequate discussion of the surgical treatment of chronic ulcerative colitis. With him, I am persuaded that diversion of the fecal stream by end ileostomy does more for patients with the severe form of this disease than anything else that I know of save total colectomy. The high mortality that was formerly associated with ileostomy in the severe forms of colitis has been markedly reduced by preoperative therapy, so that it now constitutes a less serious objection to this method of therapy. Excoriation of the abdominal wall has remained, however, a troublesome complication. To ameliorate this condition, some ten years ago I introduced a type of end ileostomy operation that has given us increasing satisfaction and has also found favor with Dr. Bargen at the Mayo Clinic and Dr. Sanders of Memphis. The ileum is transected just proximal to the ileocecal valve and the distal end closed. The proximal portion is brought out through a stab wound in the abdominal wall for a distance of 4 inches (10.2 cm.) and is covered with a skin graft. The graft takes readily. The ileum may then be trimmed to the desired length to permit discharge of the ileal content into the apparatus without coming in contact with the skin. I am very interested in Dr. Dennis' experience with vagotomy in the treatment of chronic ulcerative colitis. He should be encouraged in this type of work. I should like to point out, however, that we do not have in this case the physiologic basis for vagotomy that we have in peptic ulcer. In the latter instance we know that an excessive secretion of gastric juice can produce the disease, that an excess of secretion of gastric juice occurs in patients and that this can be reduced by sectioning the vagus nerve. In chronic ulcerative colitis we have some evidence that central nervous system factors exert perhaps an inciting or aggravating effect, but we have not succeeded in producing the disease in experimental animals. I should like to refer to a fact that is a little discouraging to me; namely, that functional bowel distress, where the role of the central nervous system seems to be definite, is seldom followed by chronic ulcerative colitis.

Dr. Everett D. Kiefer, Boston: The concept that regional ileitis and ulcerative colitis are the same disease, differing only in the level of the intestinal tract which is involved, is an attractive one from the clinician's point of view. Acute enteric infections, bacillary dysentery, amebic dysentery, food allergy and emotional trauma have all been indicted as a cause of ulcerative colitis. However, the common denominator, possibly a constitutional factor, which determines why one case in an epidemic of acute colitis goes on to chronic ulcerative colitis while in 99 others there is complete recovery, remains a mystery. It has often been said that ulcerative colitis tends to begin in the rectum and progresses in a retrograde direction over to the cecum. Actually, I have observed this in only rare instances. A patient usually presents himself with involvement of either a segment of the bowel or the entire colon, and subsequent roentgen and proctoscopic examinations may show variations in the degree of involvement, but the anatomic limits of the diseased area remain exactly the same. There is no specific or reliable medical cure for either regional ileitis or ulcerative colitis. Improvement in nutrition, control of the diarrhea, treatment of the anemia, hypoproteinemia and secondary function help to promote remissions of active disease and adjustments of function to the damage already done. It is more accurate to speak in terms of control of the disease rather than cure. It has been our experience that in approximately one half of the patients with ulcerative colitis the disease can be controlled by conservative measures, but the other half go on with either partial or total disability, and a large percentage will eventually die of the disease. I would emphasize the most important indication for surgical treatment; namely, chronic invalidism. The clinical results which follow ileostomy in these cases are usually striking, with the patient returning to his occupation and normal place in society. The price that the patient must pay for the cure of his disease is permanent ileostomy. To the layman this price seems a horrible one. Our experience, however, has been surprisingly happier, confirming the experience reported by Dr. McKittrick. With proper selection of cases the patients and their families are grateful and consider their relief well worth the price. Recently Dr. David McKell, of our clinic, has questioned 84 patients with permanent ileostomies; 79 were pleased with the results and said that they wished the ileostomy had been done sooner, and only 5 regretted having it done. When cases are selected judiciously, surgical treatment offers more to the colitis invalid than any other treatment. The therapy of chronic regional ileitis is even more unsatisfactory than that of chronic ulcerative colitis. Since medical management is ineffective in many cases of chronic disease, surgical treatment has been employed. However, recurrences have plagued the surgeon.

Dr. J. H. Fitzgibbon, Portland, Ore.: I should like to make a small contribution to the confusion in regard to etiology, by bringing up again the subject of familial incidence which Dr. Crohn touched on. Little has been written about familial incidence. I think it might be worth while to tell about one family with which I have had intimate contact. There were 4 brothers, 1 of whom died of ulcerative colitis. The second, the first member of the family whom I saw as a patient, had been treated previously and operated on for regional ileitis. He later died, after his second or third operation for regional enteritis. Two brothers are now under my care. One has had an ileostomy which he feels saved his life; the other has intermittent flare-ups of ulcerative colitis and had a fistula operated on recently. One sister died of ulcerative colitis. Another feels that her life was saved a year ago when an ileostomy was done. I have treated a cousin—a female—with ulcerative colitis, on whom an ileostomy was done. She feels it was lifesaving. Her son, a boy of 10 or 12, was seen early in ulcerative colitis and has made a splendid response to medical treatment. In regard to the psychogenic aspects, one member of the family insists that his flare-ups have been assocated with emotional tension.

Dr. A. F. F. Andresen, Brooklyn: The cause of ileitis and ulcerative colitis is not entirely unknown. While many cases are due to specific organisms, in our experience about 60 per cent have been proved to be due to allergy. The allergic reaction may be due not only to sensitization to food or other ingesta but to bacteria (as in focal infections) and to inhalants (pollens and the like). To produce the marked reaction in these diseases, the exciting cause must be constantly operative; that is, the food or other agent must be eaten, inhaled or absorbed every day. It is not easy to establish an allergic cause for ulcerative colitis. It requires much patience and perseverance in working out the case, but with this principle carried out we have been able to clear up the disease and to avoid operation. The results have been as good as with any other allergic condition. I do not believe that psychosomatic surgery—that is, vagotomy, which is clearly a psychosomatic approach from the surgical standpoint—is of any particular interest in a case of this sort, and I believe that other operations for ulcerative colitis should be done only for complications, even though we have been told that ileostomy is such a great incentive to matrimony.

Dr. Leland S. McKittrick, Boston: I should like to thank the discussers for their contribution to this program. I have only one additional comment. Much has been said about the similarity between so-called regional enteritis and what I understand as ulcerative colitis. I do not feel competent to offer any contribution relative to the similarity or dissimilarity of these two diseases pathologically, but I do know that they are quite unlike clinically. We have great confidence that we can offer complete and lasting freedom from the disease to most patients who survive the necessary operations for ulcerative colitis, and to the patient with the disease which I know as regional enteritis, surgery offers the hope, but not expectation, of a cure. They may be similar pathologically, but they are certainly different therapeutically, and, after all, the patient comes to you and to me for therapy.

# IDIOPATHIC ULCERATIVE COLITIS

## Newer Concepts Concerning Its Cause and Management

SIDNEY A. PORTIS, M.D.
Chicago

Early uncomplicated and localized idiopathic or nonspecific ulcerative colitis, I think, originates in early childhood, although the pathologic or pathologic-physiologic picture may not become evident until adolescent or adult life. The fact that the changes in the bowel wall begin for the most part in the rectum and sigmoid and spread upward to include the ascending limb of the splenic flexure has been passed over lightly in the discussion of this subject. There are many etiologic conceptions and varied therapeutic approaches. I have never been convinced that any specific organism is the cause.

Five years ago I became interested in the increasing reports in psychiatric literature of presumable cure of uncomplicated and early ulcerative colitis. Psychiatrists claimed they could produce a lasting remission; this I consider a challenge. What did psychiatry accomplish that medicine could not? I could conclude only that the treatment had normalized the physiologic picture of the gastrointestinal tract, especially of the sigmoid and rectum, and that this had led to healing.

I directed my attention to a limited portion of the colon which became ulcerated. The proctoscopic and the roentgenologic picture are pathognomonic, with tubulization of the rectosigmoid and even the descending colon. The haustral markings are lost; the outer aspect of the bowel wall here has a "feathery edge" or fine "saw-tooth" configuration. Pneumocolon shows fine flecks of retained barium if ulceration has taken place. (Air must not be forced into the colon with too great pressure, since perforation has resulted from too much and too vigorous inflation.) With the foregoing objective observations, I had a tangible beginning for observing and evaluating the progress of the disease.

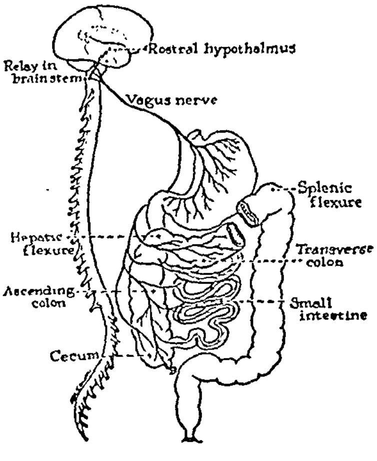

Fig. 1.—Vagal innervation of the gastrointestinal tract up to the ascending limb of the splenic flexure.

Questions to be answered were: Why does this disease begin in the rectum and sigmoid and spread upward diffusely, with no portion of the mucous membrane in the involved areas escaping pathologic change? What happened to the mucous membrane here which lowered resistance and led to ulceration? The normal protective mechanism must have been interfered with to allow the disease to develop.

Most doctors believe today that this disease which starts in the mucous lining of the bowel wall spreads to the deeper layers. Apparently this inflammation is not hematogenous or thromboembolic. The thrombophlebitis seen on microscopic section of the colon is retrograde and not primary. The embolic manifestations or thrombi in the small arterioles feeding the gut have not been established as primary. The organisms found on culture from the stools or on direct smear are as a rule normal inhabitants of the fecal flora.

Therefore, this disturbance in normal physiologic balance must have started in the mucous lining. Several methods of approach were possible. If the psychiatrists were correct in their observations, then the first inquiry had to do with the nerve supply of the gastrointestinal tract, especially the colon.

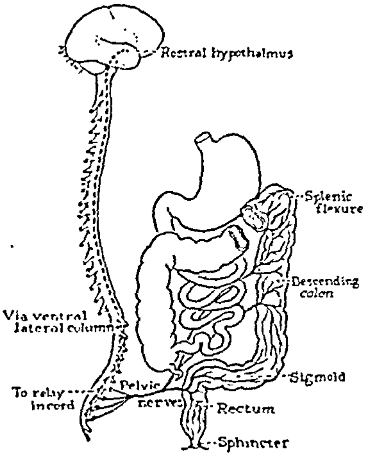

Fig. 2.—Sacropelvic innervation of the colon from the rectum up to and including the ascending limb of the splenic flexure.

Anatomically, the colon has four different sources of nerve supply: (1) the vagus nerve (cholinergic), whose parasympathetic fibers supply it from the cecum up to the ascending limb of the splenic flexure (fig. 1), (2) the sacropelvic (cholinergic) nerve, which supplies the colon from the end of vagus innervation up to and including the rectum (fig. 2), (3) the sympathetic (adrenergic) nerves which supply the whole colon and are derived wholly from the spinal cord and (4) Auerbach's plexus (cholinergic), that intermediary plexus which transmits impulses to the cellular structure.

In this disease the parasympathetic (cholinergic) system—namely, the vagus and sacropelvic nerves—is most important. The vagus arises from the medulla and through its branches directly innervates the bowel. The sacropelvic nerve is formed into a nerve from the central area of the cord—between the second and the fourth sacral—and supplies the pelvic organs, including that portion of the colon described. Since emotional stimuli are transmitted over both these nerves, the end physiologic effect of overt stimulation is a disturbance in physiologic balance. The motor nerve, e. g., the vagus, causes contraction and peristalsis of the small intestine and relaxation of the ileocecal valve. The colon in turn has increased motility, for the same reason, up to and including the ascending limb of the splenic flexure. The sacropelvic nerve has the same physiologic effect on the distal part of the colon as the vagus nerve has on the ileocecal portion.

I have never observed a case of ulcerative colitis in which motility of the descending colon, sigmoid and rectum was normal, even though the small intestine and the colon up to the ascending limb of the splenic flexure were hypermotile. Therefore, it is important to recognize that in the early and localized form of this disease the sacropelvic nerves and their innervations in these structures are a prime source of the physiologic disorder.

Apparently, this disease is limited in the early stage to that portion of the colon innervated by the sacropelvic nerves (figs. 3 and 4). Why does it not invade

Read before at the Ninety-Seventh Annual Session of the on, Chicago, June 24, 1948.

the part innervated by the vagus? Certainly most physicians have seen the entire colon involved in the chronic form. It would appear that altered emotional stimuli are transmitted principally over the sacropelvic nerves at the outset. Yet the same physiologic abnormality can be produced at the nerve endings of the mucous lining of the whole gastrointestinal tract. It must be postulated that in the early stages a protective mechanism exists in the mucous lining of that portion of the colon innervated by the vagus nerve, while the portion innervated by the sacropelvic nerves is more susceptible. The altered emotional stimuli are transmitted over both nerves. After the disease progresses beyond the splenic flexure into the transverse colon, vagal influence with decreased protection may play a similar role.

The concentration of pancreatic enzymes in the lower part of the ileum and cecum is of a high titer. There must be some attenuation or binding or destruction of these enzymes as they pass down through the colon, so that by the time they reach the descending colon they do not have the same digestive activity. A normal alkaline stool does not cause burning or smarting at the anal orifice if the gastrointestinal tract has normal motility. During an attack of acute diarrhea there is usually smarting or burning. If rapid motility of the gastrointestinal tract persists long enough, the skin about the anal orifice becomes red, painful and swollen like that about an ileostomy wound. The fresh skin about an ileostomy, however, has a tendency to bleed easily: this must be due to a difference in concentration of pancreatic enzyme. When the stools of diarrheal patients are examined for trypsin, the titer is never so high as that of fecal matter from an ileostomy. The concentration of trypsin in the intestinal contents pouring out of the ileum of a recent ileostomy patient is 50 times that in the stools of a patient with ulcerative colitis. Later on, as the ileum assumes some of the function of the colon, the concentration may drop to 10 or 15 times that of the patient with colitis.[1]

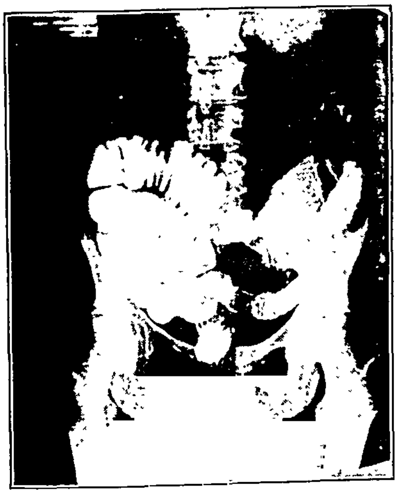

Fig. 3.—Ulcerative colitis limited to the part innervated by the sacropelvic nerves.

The recent reports that bilateral vagotomy produced definite improvement in the clinical picture of ulcerative colitis add weight to the assumption that the titer of pancreatic enzymes is a factor in this disease. This improvement can be due only to the slowing down of peristalsis in the small intestine and first part of the colon. Neither of these portions of the gastrointestinal tract is involved in the early picture of this disease.

The similarity of the proctoscopic picture of the early involved mucous membrane to the skin of an ileostomy patient led me to believe that increased concentration of enzyme was an important factor which produced digestion in both conditions. Experimental studies in dogs produced too many variables to allow any conclusion as to the concentration of these mixtures. More careful work in future studies should shed more light on this phase of the subject.

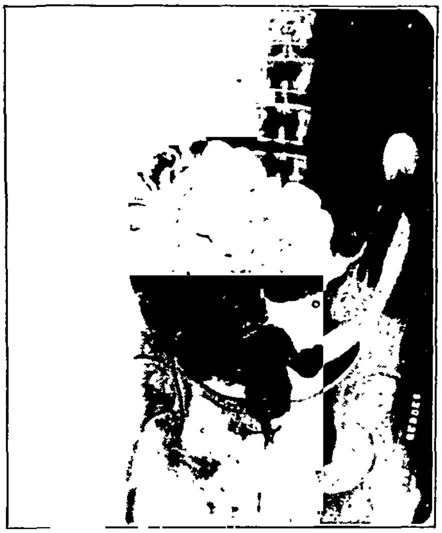

Fig. 4.—Roentgenogram taken two years and eight months after figure 3, showing that the disease had not progressed beyond that portion subserved by the sacropelvic nerves.

The mucous membrane in early and even in late ulcerative colitis is hyperemic and swollen, has a cooked appearance and bleeds easily with such slight trauma as brushing with a cotton swab. The pinpoint hemorrhages resulting from swabbing early in this disease are diagnostic, occurring in no other disease where macroscopic ulceration does not exist, except acute bacillary dysentery.

The mucosa of the intestinal tract is covered with mucus secreted by its glands. The complex carbohydrate mucin probably serves chemically and physically to protect the lining cells from enzymes and acids. Liquefaction or hydrolysis of mucin is produced by the mucolytic enzyme lysozyme, which is normally present in the intestinal tract and the concentration of which may change in gastrointestinal disorders. It is obvious that an increased concentration of lysozyme may mean lysis of mucus, and therefore an increased attack by enzymes on unprotected mucosa.

Recently, Meyer, Gellhorn, Prudden, Lehman and Steinberg[2] have shown a mean lysozyme titer for normal stools of 2.7 units. Normal stools after purging showed 1.6 units. The mean titer of stools from patients with chronic ulcerative colitis was 56 units. Even more striking was the high titer of lysozyme found in specimens of mucus obtained from the rectosigmoid region of patients with this disease, a mean of 158.1 units. On the other hand, the ileal stools of 3 patients after ileostomy showed a mean titer of 2.8 units. The highest total of lysozyme content noted in the feces of a control group was 528 units in twenty-four hours, whereas the lysozyme secretion of ulcerative colitis patients was as high as 44,400 units in a comparable period (table).

[2] Meyer, K.; Gellhorn, A.; Prudden, J. F.; Lehman, W. L., and Steinberg, A.: Proc. Soc. Exper. Biol. & Med. 65: 221-222, 1947.

Meyer and co-workers [3] studied 5 patients with peptic ulcer before and after vagectomy. The mean fall in the titer was 44.4 per cent, with a range of 16.7 to 74.4 per cent. This, they concluded, indicates that lysozyme production is at least partly influenced by nervous control. Apparently, in ulcerative colitis the emotional stimuli transmitted to the rectum and sigmoid by the sacropelvic nerves produce more lysozyme than is normal for the mucous membrane of the rectum and sigmoid, and the mucous protection of the sigmoid and rectum is definitely lowered by this mucolytic enzyme. The lowered resistance of the mucous lining may allow tryptic digestion and invasion by bacteria apparently innocuous to a normally protected mucous lining. The increased peristalsis of the small intestine and colon would throw more tryptic enzyme down on an unprotected mucous membrane. Ulceration is the result of enzyme digestion.

The disease process, therefore, is comparable to peptic ulcer except that it is diffuse rather than isolated.

*Lysozyme Assays of Normal and Pathologic Stool Specimens*

| Source | Individual Lysozyme Titers (Units per Gram, Wet Weight) | | | Mean Lysozyme Titer |

Because this discussion suggests that ulcerative colitis may be the result of a pathologic mechanism originating in the emotional centers of the brain, it might be well to inquire into observations on the emotional factors in this disease.

Alexander [4] described the process by which the child in early life loses his sovereignty over his excremental functions during training to cleanliness, when adults try to influence him to defecate at regular intervals—for the child a compliance with the adult's wishes. The child may receive in exchange praise, love and sometimes even more material good, such as a piece of candy. Thus the excrement becomes first associated with the concept of possession, and its close relation to money, one of the best established facts of psychoanalysis, can be explained easily on this basis. The child can evaluate his excremental acts as a kind of donation to the adults, and the concept is often reinforced by the mother's great interest in the matter. (The German expression for the bowel movement of the child, *Bescherung*, means gift.)

In the early period the child's attitude toward excrement is coprophilic. The excrement is a valuable possession, a source of pleasure and something which can be exchanged for other goods. This coprophilic attitude, however, soon is changed by educational procedure to its opposite, disgust and depreciation. This becomes, then, the basis of the sadistic aggression and soiling connotation with the excremental act. The excrement becomes a soiling weapon, and the act itself has assumed a depreciatory significance. This can be observed most clearly in the little street urchin who defiantly shows his hindparts and often accompanies this gesture with some kind of aggressive invitation. All these emotional connections, of course, more or less disappear in later life from the conscious personality, but they remain deeply rooted and often appear among the neurotic symptoms of mentally disturbed patients and even in the dreams of normal adults. Apparently, from the evidence of Alexander, the establishment of correct bowel reflexes leading to expulsion of stool must travel over the sacropelvic nerves. Therefore, one would expect that the primary area attacked in emotional disturbances associated with defecation would be the area subserved by those nerves: only later would the pathologic changes spread upward into the field of vagal innervation of the colon.

Other constellations of emotional factors also may produce this disturbed physiologic balance, but they have not been so clearly worked out or tabulated for statistical evaluation.

It is of clinical interest that this psychologic explanation of early infantile bowel habits can be demonstrated in adults. For instance, a young woman married for six months began suffering from early ulcerative colitis. Under medical management, later to be discussed, the bowel had become entirely quiescent—no blood, normal formed stools and a feeling of well-being. After three months of medical management she complained to me, one Monday, of a precipitous recurrence of her diarrhea on the preceding Sunday morning. Careful interrogation revealed that she had had no undue excitement on the previous Saturday evening. She had eaten at home on Saturday and Sunday, followed her diet and taken her medicine as directed. About one hour after breakfast, while she was working around the home, diarrhea appeared. I know from clinical experience that diarrhea cannot occur in a well managed subject who has no intercurrent infection, unless there has been overt emotional stimulation of the presumably stabilized emotional system. Therefore, I questioned her on the life situations of that Sunday morning when she was at home with her husband. She denied any unusual happening, but further prying revealed that her husband asked her, facetiously or otherwise, "What about the $400 I loaned you when we first got married to buy your trousseau? When am I going to get it back?" She did not have the $400. She felt distinctly disturbed, regressed into a childhood pattern and immediately had diarrhea. When I pointed out to her the association with the money and her inablility to give it back except with bowel movements, the condition immediately cleared up—with no change in diet or medical management. This patient subsequently went through an entire pregnancy without further recurrence of symptoms.

Another similar but more complicated life situation was that of a civic-minded attorney in a small town. He had had ulcerative colitis for two years. His stools were free from occult or gross blood for a year and one-half under management, and for two months he had not received any drugs and was leading a well

4. Alexander, F., in Portis, S. A.: Diseases of the Digestive System, ed. 2, Philadelphia, Lea & Febiger, 1945, p. 838.

regulated life with no particular dietary restriction. He concocted the idea that the church should assume the responsibility for the afternoon play of the school boys, and a deficit of $600 accrued. He went to the lodge of his community and told them of the deficit, and was told that he had engineered the scheme and that the lodge did not have the money. Simultaneously with the inability to furnish funds his diarrhea recurred. When the interpretation heretofore outlined was given to him, his bowel movements became normal after a few weeks' management and have since remained so.

A more striking case is that of a 19 year old student who was being given combined medical and psychiatric management at the hospital. He was having twelve stools during the day and six to ten stools at night before and during the early hospital period. He had had ulcerative colitis since the age of 9. His bowel movements narrowed down to one a day and none at night while he was in the hospital. I quote from the notes of the psychiatrist:.

> After the sixth interview I was told by you that he was medically under control. I thought that I could try some interpretive material which might precipitate some reaction. During that interview the patient protested the fact that he was so dependent on his parents, he felt badly that he had to take so much from them, he felt badly that they had to supply all of his needs. I then told him that I thought the reverse was true, that in reality he wished to take from them, wanted to be dependent, wanted them to take care of him. He immediately asked to be excused, saying he had to go to the toilet, and subsequently showed a reaction that was diarrheal in character.

After he returned to his room, no more bowel movements occurred that day.

In the more superficial disorders, the emotional patterns can be handled by careful painstaking interrogation. The more deep seated, the more complex emotional patterns should be handled by a psychiatrist. I sound a solemn note of warning. Once this disease is diagnosed, medical management should be vigorously employed, and at no time should a psychiatrist be allowed to treat a patient with ulcerative colitis without rigid medical control. The disease is too treacherous to be handled by the psychiatrist alone. Perforation and hemorrhage can and do occur without rigid medical control. No psychiatrist can control the emotional problems twenty-four hours a day. Therefore, I repeat that combined management, if a psychiatrist is needed, is the only safe treatment.

## MEDICAL MANAGEMENT

The therapeutic approach to this problem should take into consideration the dietary aspects, the medicinal or pharmacologic agents and psychiatric treatment, if needed.

*A. Diet.*—The diet for ulcerative colitis is outlined:

Foods Allowed

| | |
|---|---|
| Cereals | One serving daily. Well cooked oatmeal and pettijohns, cream of wheat and farina. Avoid cereals containing bran, e.g., "all-bran" "shredded wheat," "muffets" and "grape nuts." |
| Cereal Substitutes | Spaghetti, noodles, rice, vermicelli, macaroni; all to be plainly prepared without the addition of any fat or highly seasoned sauces. |
| Breads | Enriched white bread, well toasted. May use melba toast, white crackers, zweiback, or holland rusk if desired. |
| Potatoes | One serving daily. May be either boiled, baked or mashed. |
| Soups | Vegetable milk soups made with puréed vegetables and milk. Avoid the use of all meat stock soups. |
| Meats | Lean tender beef, lamb, liver, dark meat of chicken or turkey.<br>Liver two times per week. Broiled or boiled sweetbreads, kidney lamb chops may also be used. None to be fried. |
| Fish | Broiled, boiled or baked lean fresh water fish, e. g., perch, pike, bass, trout or whitefish. At least once or twice per week. May have fresh boiled shrimp if desired without garnish. |
| Cheese | Cottage, cream, mild American and Wisconsin brick cheese. No other kinds of cheese to be used. |
| Eggs | One or 2 daily, soft cooked, poached or soft scrambled over low flame. None fried. |
| Vegetables | All vegetables are to be thoroughly cooked and puréed. Use leafy green vegetables, e. g., spinach, and greens (puréed) liberally.<br>Avoid the use of all raw vegetables. |
| Fruits | May have canned or stewed fruit (all to be puréed EXCEPT peaches and pears). Avoid syrup of canned or stewed fruit. Use puréed prunes and strained orange juice frequently. NO raw fruits or fruits with tough skins, fibers, and seeds. |
| Desserts | Fruit as aforementioned, fruit gelatin, rice pudding (no raisins), tapioca, junket and custard. |
| Beverages | At least 3 glasses of milk daily, buttermilk or acidophilus milk occasionally. |
| Condiments | None except salt in moderate amounts. |

Foods to Avoid

Coffee, tea, alcoholic and carbonated beverages, cocoa and tobacco.
Raw fruits and vegetables, berries, syrups or canned fruits. Fried foods, oils, salad dressings, cream, nuts, peanut butter, pork and pork products. Gravies and sauces. Spices and condiments.
Tinned or luncheon meat and fish.
Candy, cake, pies, pastries, sugar, jelly, honey, syrup and jam.

Use "cellu" sugarless sweetener or saccharine instead of sugar.

The following outline is of a sample menu for ulcerative colitis:

| | |
|---|---|
| Breakfast | 6 oz. strained orange juice<br>½ cup well cooked oatmeal<br>4 oz. milk<br>1 soft cooked egg<br>2 slices white toast<br>1 pat butter<br>6 oz. milk<br>No sugar |
| 10 a.m. | 6 oz. tomato juice<br>1 slice white toast<br>1 pat butter |
| Luncheon | 4 oz. cream of pea soup<br>Broiled whitefish, 3 oz.<br>Boiled potato<br>Puréed green beans<br>2 slices white toast<br>1 pat butter<br>Fresh strained applesauce (no sugar)<br>6 oz. milk<br>No sugar |
| 3 p.m. | Canned peaches, no syrup<br>2 unsalted white crackers |
| Dinner | 3 oz. tomato juice<br>3 oz. broiled calves' liver<br>Baked potato (no skin)<br>Puréed spinach<br>Puréed lima beans<br>2 slices white toast<br>1 pat butter<br>Baked cup custard<br>6 oz. milk<br>No sugar |
| Bedtime | 4 oz. rice pudding<br>6 oz. milk |

| | |
|---|---|
| Protein (Gm.) | 123 |
| Fat (Gm.) | 92 |
| Carbohydrate (Gm.) | 305 |
| Calories | 2,540 |

From the outset the patient is fed easily digestible foods which leave little or no residue. Because of rapid passage of the food through the gastrointestinal tract, absorption is impaired; therefore the diet is high in protein, calories, vitamins, iron and carbohydrates. The high iron content is advisable also to replace iron lost by hemorrhage from the ulcerative surfaces. Fats usually are not well tolerated and are used moderately. Omission of free sugar in any form was based on twofold evidence: First, slow injection of dextrose in normal dogs greatly increases the tolerance of these animals to subsequent more rapid injection, and second, the deaminization of protein and the formation of carbohydrate go on at a much slower rate in the liver of patients with colitis and therefore will give a more prolonged secretion of glucose over a long period, and postdigestive hypoglycemia will be delayed if necessary to the next intake of food. However, more frequent feedings than the normal three meals a day were used as an additional factor of safety, to prevent hypoglycemia, and a feeding was given at bedtime to prevent hypoglycemic manifestations between the last regular meal at night and breakfast. The patient receives his three main meals, a midmorning feeding, one or two midafternoon feedings and a feeding before he retires at night.

My studies led me to believe that physiologic disturbances of the gastrointestinal tract respond best when circulating sugar in the blood is high at all times. This has been previously emphasized in the treatment of peptic ulcer and patients suffering from fatigue.[5] One of the most important functions of food is to keep the brain adequately supplied with glucose. This continuous nourishment has a salutary effect on an emotionally disturbed brain. The tendency to relative hypoglycemia is revealed by an intravenous glucose tolerance test. The blood sugar level at the end of three hours is lower as a rule than the initial fasting value.

Smoking is prohibited, because it prolongs hypoglycemia after the initial rise of the level of blood sugar, defeating the purposes of this diet.

*B. Medicine.*—1. Atropine sulfate is the drug of choice. It paralyzes the vagus and sacropelvic parasympathetic nerves and usually blocks out impulses from the emotional centers of the brain. Only when excessive stimulation comes over these nerves does an impulse get through to the intestines. The drug may be given to adults in doses varying from 1/200 to 1/50 grain (0.33 to 1.3 mg.) three times at meals and a fourth time at bedtime. The bedtime dose is exceedingly important for the blocking out of emotional disturbances carried over these nerves while the patient is asleep. Furthermore, ten hours may elapse before the next intake of food.

2. Phenobarbital is given in doses of from ¼ to ¾ grain (18.2 mg. to 49 mg.) three times a day at meals and a fourth time with the bedtime meal. The barbiturates tend to produce a quiescent emotional household.

3. Sodium alkyl or lauryl sulfate, in doses of 100 to 200 mg., is given three times a day. (If excess pancreatic enzyme and bacterial trypsin are present, they can be bound with one of these wetting agents.) In a recent verbal communication Karl Meyer stated that these wetting agents bind lysozyme and make it inactive. Observations on a large number of patients lead me to conclude that this is an important therapeutic agent. It is best given in enteric-coated pills to escape combination with gastric enzymes and prevent nausea. I have used it in ordinary capsule form, but the present preparations have many impurities and may not be well tolerated. More chemically pure preparations of these wetting agents are in the process of manufacture.

4. Sulfonamide drugs inhibit to some extent the bacteria which take their toll on the unprotected mucous lining of the affected portion of the colon. My personal choice among them is phthalylsulfathiazole, given in doses of 15 to 30 grains (1 to 2 Gm.) three times a day. This produces a low concentration of the sulfonamide drug in the blood stream and a high concentration in the bowel content. Antibiotics have little, if any, value in the nonfulminating form of this disease. Phthalylsulfathiazole should be used only at the outset and for short periods, because normal inhabitants of the gastrointestinal flora manufacture parts of the vitamin B complex, particularly pantothenic and folic acid, the latter necessary for hemopoiesis. Elvehjem[6] has shown that if the gut of young puppies is sterilized with sulfonamide drugs, growth ceases, because of vitamin deficiency.

5. Crude liver extract, 2 cc. three times a week intramuscularly, furnishes a high concentration of the whole vitamin B complex, of distinct benefit to the patient. There is some clinical evidence that it is beneficial to liver metabolism as a whole and, therefore, produces a better physiologic balance of the liver. Thiamine chloride should be restricted to small doses, because it may be laxative.

6. Contraindicated drugs include bismuth, kaolin and kaopectate, which are dangerous in any form because caking of the fecal content may cause pressure necrosis and perforation. Opiates are rarely needed, but 10 to 15 drops of tincture of opium one to three times a day is the preferable form. I rarely use any opiate.

Acutely ill patients should be hospitalized, but others may be treated while ambulatory. Hospital or ambulatory management is the same, as a rule. However, in the presence of severe anemia with a low level of plasma proteins, transfusions of whole blood, plasma and electrolytes with dextrose may be indicated early. As the disease gets under control, these emergency measures are not needed.

The type of case selected for medical management is usually one in which damage to the bowel wall has not been too severe. However, even when damage has been considerable, vigorous medical and psychiatric control should be tried. I do not see tubular constricted and perforated colons any more, although other clinicians may still see them. The fact that chronic tubulated, extensively involved colons do come to one's attention is a sad reflection on the medical management previously given to these patients. Therefore, I repeat: One cannot point with pride to the resultant incidence of morbidity and mortality.

If the colon is beyond medical repair, surgical intervention may be indicated. The type of operation should be decided by the combined judgment of surgeon and internist. The psychiatrist becomes an interested observer during the surgical phase. Modified medical management should follow the operation, with choice dependent on the type of surgical treatment. I might add parenthetically that I do not think ileostomy is of any particular value in the acute fulminating phase of this disease. It accomplishes nothing which cannot be accomplished with the present pharmacologic and parenteral therapeutic approach.

## RESULTS OF MANAGEMENT

Five years of continuous experience have led to the conclusion that the medical management outlined for early and uncomplicated ulcerative colitis is the safest and most satisfactory treatment.

The regimen affords the opportunity of rigidly controlling the patient at all times, observing the progress of the disease through the proctoscope and noting complete healing when the rectum and sigmoid mucosa no longer bleed when swabbed with cotton. This disappearance of bleeding on trauma is one of the most accurate criteria that the mucous membrane is no longer the seat of this disease. Roentgenologically there is no irritability, the feathery edge of the colon disappears; haustral markings may reappear, and flecklike ulceration on pneumocolon is no longer evident.

---

[5] Portis, S. A.: Medical Treatment of Psychosomatic Disturbances, J. A. M. A. **126**: 413-417 (Oct. 14) 1944.

[6] Elvehjem, C. A.: J. Am. Dietet. A. **22**: 959-963 (Nov.) 1946.

Thus the lower part of the colon is restored to a near normal pattern.

In my experience, only under this management can the psychiatrist be allowed to go at the emotional household as hard as he pleases without doing the patient harm. I have seen acute fulminating complications arise when the psychiatrist alone has treated the disease. Finally, I am led to believe that of all the diseases of the gastrointestinal tract for which combined medical and psychiatric control is desirable, nonspecific ulcerative colitis lends itself to the most lasting and satisfactory result.

## CONCLUSIONS

1. Emotional stimuli from the hypothalamic region are transmitted through the spinal cord and are carried by the sacropelvic nerves to the rectum, sigmoid and descending colon up to and including the ascending limb of the splenic flexure.

2. Lysozyme (a mucolytic enzyme) is partly influenced by nervous control. The increased stimulation by the sacropelvic nerves presumably produces a higher titer of this enzyme. The loss of mucous protection allows the digestive activity of the trypic enzyme from the pancreatic secretion and bacteria to take their toll on the mucous membrane.

3. Ulceration results from this pathologic-physiologic change.

4. Treatment should (*a*) be directed at the eradication of the emotional stimuli, (*b*) paralyze the sacropelvic parasympathetic nerves with atropine sulfate and (*c*) abolish cortical inhibitory influences on the hypothalmic region by the use of barbiturates; (*d*) enzymes should be bound by wetting agents as sodium alkyl sulfate to prevent their digestive activity; (*e*) sulfonamide drugs should be given cautiously and only for limited periods.

5. Psychotherapy should be accompanied with rigid medical control at all times.

## ABSTRACT OF DISCUSSION

Dr. Franz Alexander, Chicago: Emotional factors in the precipitation and clinical course of ulcerative colitis have been repeatedly stressed by a number of experienced clinicians. Very little specific was known, however, about the nature of the emotional factors involved. The pathophysiologic mechanism by which these emotional factors influence the mucous membrane of the large bowel were equally unknown. Dr. Portis has succeeded in indicating specific psychologic and somatic factors. His observation concerning the initial localization of ulceration in the lower portion of the colon, which is under the nervous control of the sacropelvic portion of the parasympathetic system, appears highly significant. It confirms the observation that the psychologic stimuli in play pertain to the excremental act. The clinical examples of Dr. Portis are convincing and correspond to the preliminary observations made at the Chicago Institute for Psychoanalysis in the course of a psychosomatic study of ulcerative colitis. In these preliminary studies, two emotional factors stand out conspicuously, both in precipitating the disease and also in provoking relapses. One is the frustrated tendency to carry out an obligation—either moral or material—and the other is the frustrated ambition for accomplishment requiring concentrated expenditure of energy. Dr. Portis' example demonstrates the first type of emotional factor. He correctly pointed out that the urge to give or to fulfil an obligation are deeply linked with the act of evacuation. For the psychoanalytically trained psychiatrist, also, the emotional connection between pride in accomplishment and the excremental act is well known. The specific psychiatric question is to explain the fixation of the patient with ulcerative colitis to the anal phase of emotional development. Once the origin of this emotional fixation is established one can easily understand that whenever in later life the urge to give, to carry out an obligation or the ambition for accomplishment on some adult social level is blocked because of neurotic inhibitions, a regression to the anal form of giving or accomplishment may take place. It should be emphasized, however, that anal regression of this type is extremely common in all kinds of psychoneurotic persons. Some specific local somatic factor must be responsible for the fact that in some patients anal regression produces ulcerations in the bowels. Some inherent weakness must be assumed, and Dr. Portis' study indicates that this susceptibility to emotional stimuli of anal regressive nature may lie in the peculiarity of the intestinal enzyme chemistry which is characteristic for these patients.

Dr. Robert J. Coffey, Washington, D. C.: Dr. Portis' paper offers a completely new approach to many perplexing problems of this disease. His views substantiate the rationale of a recently proposed surgical attack on chronic ulcerative colitis, namely, interruption of the vagus nerves. This procedure is, I understand, now being limited to early phases of this condition and, as in the case of peptic ulcer, is to be viewed at the present time only as a "justifiable experiment." I wonder whether interruption of the sacropelvic outflow of the parasympathetic nervous system should not be used to supplement vagotomy in this work. The merit of any such procedure applied to the early phases of this condition is subject to doubt and criticism, as many other proposed forms of therapy have been at times successful and spontaneous regression and cure not infrequently occur. Dr. Portis stated that this is essentially a medical disease, a view which I, as a surgeon, whole-heartedly share. It is only for the advanced manifestations that surgical treatment is indicated. Among the usual indications for surgical treatment are: (1) Intractable, insanguinating hemorrhage, for which ileostomy may be used in desperation. This is, in my opinion, a rare occurrence. (2) Advanced and diffuse involvement of the colon in which the organ becomes a badly scarred, narrow tube. My feeling is that even in these advanced cases, total colectomy, with a permanent ileostomy, is rarely justified. (3) Localized ulcerative colitis, in which the rectum and lower sigmoid are relatively uninvolved—this situation is rarely encountered, but when present, permits of segmental resection of the involved portion, the results of which are uniformly good. (4) Polyposis. Dr. Bargen, of the Mayo Clinic, and I demonstrated that there is a 10 per cent incidence of polyps in chronic ulcerative colitis. These polyps have been previously regarded as pseudopolyps or inflammatory tags of mucosa following an extensive ulcerative process. However, our studies revealed that true adenomatous changes develop in about 20 per cent of the cases in which polyps develop. These adenomatous changes are usually recognized grossly by the exuberant vascular appearance of the polyps in distinction to the pale fibrous appearance of the commoner pseudopolyps. As pointed out by Bargen, the incidence of carcinoma in chronic ulcerative colitis is 2.5 per cent, and this percentage of malignant disease occurs almost exclusively in the group in which true adenomatous polyps develop.

Dr. Peter D. Comanduras, Arlington, Va.: This disease is a strange and complex malady. Certain factors must be known before any final evaluation of this disease can be justified. First, the causation is not known. Secondly, it is a chronic disease with remissions and relapses, most often spontaneous. It may manifest itself in various forms at different times in the same person or in different persons. There is another type of the disease which is frightening—the acute type with exsanguinating hemorrhages which in a few hours to a few days may result in death. A third type is progressive, unrelenting in its character and intensity, becomes worse despite all treatment and may result in death within a few weeks to a few months. The word "cure" must not be used at the present time in this disease; probably "arrested stage" is a better term. The observation of lysozyme in increasing amounts in peptic ulcer and ulcerative colitis is most interesting. Blood transfusions should be used repeatedly and frequently. Two thirds of the patients with ulcerative colitis respond to medical treatment. One third will not improve. Of these, two thirds will probably die and one third get worse. However, operation does not have much to offer. It has been stated that of those who have been operated on, two thirds will be dead after a few years. Recently it has been stated that out of 141 patients, over a period of five years, only 5 were feeling better at the end of five years. One needs all the art and science one may have in order to treat these patients. In using that art and science, one thought should be uppermost in mind—do not harm the patient. One needs patience and, above all, an infinite knowledge of human nature.

Dr. Sidney A. Portis, Chicago: Dr. Coffey raises the question about vagotomy in ulcerative colitis and the possibility of also interrupting the sacropelvic outflow of the parasympathetic nervous system. I see no indication for vagotomy in early ulcerative colitis unless the patient does not respond to treatment with such paralyzing drugs as atropine or a similar pharmacologic approach. Secondly, if the patient is psychologically unanalyzable, the vagal influence could be abolished by vagotomy. All vagotomy does in these patients is to prevent emotional stimuli from reaching the gastrointestinal tract up to the ascending limb of the splenic flexure or Cannon's point. I do not believe that Dr. Coffey understood the validity of my premise in trying to maintain a high blood sugar content at all times and prevent overt stimulation of the islet cells by the use of paralyzing drugs, such as atropine. Furthermore, insulin and pancreatic enzymes are not simultaneously secreted by stimulation of the vagus nerves. In other words, there is no evidence of any hypersecretion of pancreatic enzymes in disturbed patients that I know of. I did not use the word "cure," and I am particularly emphasizing that this presentation is "concepts" and not necessarily "proofs." Dr. Comanduras discusses the problem about getting two thirds of a group of patients well and one third of the group do not respond at all to treatment. It is this 33 per cent morbidity which I think is a challenge to the profession. Mortality and morbidity figures of 30 to 40 per cent are no credit to any of us. When we get these figures below 5 per cent then we are doing a real job. I think that we are beginning to understand what is going on in the colon—that we might be able to prevent this pathologic-physiologic condition from progressing to the extent that there will be a severely damaged colon. There is, at least, a ray of hope that this devasting disease with its chronic invalidism and even subsequent surgical treatment may be completely abated at the outset and the colon returned to a near normal status.

---

**The Soul of Good Doctoring.**—Begin to cultivate this gift of sympathy early. Sit down on the lockers of the patients who are allotted to you and talk to them. The experience will surprise you—and it will probably surprise the patient! A good deal has been said about the doctor-patient relationship; I've said a good deal about it myself. But since it is the very soul of good doctoring, its importance can never be exaggerated. One of my chief reasons for distrusting the "new look" recently given to British Medicine is its tendency to disregard the "close-up" which is so important between doctor and patient. Availability of Medicine to all the people is a good idea. I am "all for it," as the expression goes. But *what* Medicine? Seeing 85 patients in a doctor's "surgery hour"—the operative word is clearly "seeing"—isn't Medicine. This is one of the results of the switchover that it is to be hoped will soon be adjusted. There are other knots to unravel. But the standard of doctoring is the thing that matters and no one can maintain that except the doctor himself.—Lord Horder, G. C. V. O., M.D. (Lond.), F. R. C. P., The Vocation of Medicine, *The Lancet*, Nov. 6, 1948.

# TOLUIDINE BLUE IN BLEEDING ASSOCIATED WITH THROMBOPENIA

J. E. HOLOUBEK, M.D.
J. V. HENDRICK, M.D.
and
W. J. HOLLIS, M.D.
Shreveport, La.

The use of toluidine blue or protamine as an aid in controlling the general tendency to bleed in thrombocytopenia has been suggested by Allen and his co-workers.[1] An anticoagulant, indistinguishable from heparin, was found in the blood of dogs that had hemorrhagic tendencies after prolonged exposure to roentgen rays. This bleeding was prevented and temporarily stopped by the intravenous use of protamine sulfate or toluidine blue. It was felt that this action was due to the ability of these substances to render heparin inactive. By titration of the blood in patients with thrombopenic purpura they showed that an increased heparin-like activity existed and that this could be neutralized in vitro by use of the dye or protamine. Later these substances were used to arrest the bleeding in patients suffering from thrombopenic purpura. It was found that no effect was produced on the platelet count or the bleeding time and that the primary effect was on the capillary permeability, thereby controlling the petechiae.

It is to show the results that we obtained with toluidine blue that the following cases are reported.

## REPORT OF CASES

Case 1.—An 18 year old single white girl entered the Shreveport Charity Hospital on June 21, 1947, complaining of bleeding from the gums and under the skin. About June 14 the patient noticed small hemorrhages under her skin. These were petechial in nature. She also noticed that her gums began to bleed. These had continued to ooze since then. Ecchymoses varied from 0.1 mm. to several inches in size. There had been no fever. There was no history of her having taken any medicine in over three years. There was no family history of bleeding tendencies. The patient had no previous attacks of this phenomenon. However, she did bruise easier than the average person. The patient had the usual childhood diseases. Her menses had been regular, and there had been no unusual menstrual flow.

Physical examination revealed a well developed well nourished white girl. There were generalized petechiae and ecchymotic areas from 0.2 mm. to 10 cm. in diameter on the arms, legs, trunk, face, tongue, tonsils and mucous membrane of the mouth. It did not involve the scleras, conjunctivas, retinas or vaginal mucosa. The eyes reacted to light and in accommodation. There was bleeding from the gums. No masses or tender areas were present in the neck. The lungs were resonant throughout. There were no rales on auscultation. There was no enlargement of the heart. The blood pressure was 120 systolic and 70 diastolic. There was a soft systolic murmur over the apex, which did not radiate. The rate was 70 beats per minute, with regular rhythm. The abdomen was normal. The spleen and liver were not palpable.

The reaction of the blood to the Mazzini test was negative. The urine was normal, chemically and microscopically. The results of the fragility test were normal. A sternal marrow aspiration on the day of admission revealed megakaryocytic

---

Dr. Holoubek is a Fellow of the American College of Physicians.

From the Shreveport Charity Hospital; Visiting Physician (Dr. Holoubek), Visiting Surgeon (Dr. Hendrick) and Medical Resident (Dr. Hollis).

[1] Allen, J. G., and Jacobson, L. [illegible] Cause of the Hemorrhagic Syndrome Associate[illegible] to Ionizing Radiation, Science **105**:388, [illegible] G.: Jacobson, L. O., and Spurr, C. L.: Some Observations on Bleeding Tendency in Thrombocytopenic Purpura, Ann. Int. Med. **27**: 382, 1947.

hyperplasia. The reaction to the Rumple-Leed test was strongly positive. Roentgen views of both wrists were essentially normal, except for early fusion of the distal, radial and ulnar epiphyses. A diagnosis of idiopathic thrombopenic purpura was made.

On June 23 the patient received 160 mg. of toluidine blue in distilled water intravenously. The following day there was a slight decrease in menstrual flow, but the bleeding from the gums continued. On June 24, 80 mg. of the drug was given, with no apparent effect. There was a slight decrease in bleeding time, but it was still decidedly prolonged. It became obvious that the drug would not stop the bleeding. The patient was given a transfusion and referred for surgical treatment. She had a splenectomy on June 26, receiving 1,500 cc. of blood during the procedure. She bled profusely during the entire time. Postoperatively she went into shock and received 1,500 cc. of blood and 1,000 cc. of plasma during the afternoon. Plasma and transfusions were continued during the next day, and she received a total of 5,000 cc. of blood and 2,250 cc. of plasma. She had a stormy postoperative course, complicated by jaundice and a low grade fever for about one month.

Postoperatively the platelets showed a rise to 540,000 and finally returned to normal limits. The bleeding time also became normal. She was discharged August 6 and has had no symptoms since then.

*Pathologic Report.*—The spleen measured 14.5 by 8.5 by 4 cm. and weighed 210 Gm. The surface was smooth and reddish blue. The cut surfaces were brick red. The malpighian bodies were not prominent, and the pulp showed little tendency to scrape away. On microscopic section the normal architecture was preserved. There was reticuloendothelial hyperplasia of the pulp and slight eosinophilia.

Case 2.—The patient, a 52 year old white saleswoman, entered the hospital complaining of weakness and shortness of breath. She stated that she had been well until about six months prior to her hospitalization. At that time she had a low grade fever and was found to have abscessed teeth and pus in the urine. She was given sulfathiazole, and the teeth were extracted. After administration of the sulfonamide drugs, dizziness and headaches developed, but these ceased when she stopped the medication. She was also found to have anemia and was given iron and liver tablets. The patient gradually improved and during the summer of 1947 was well and able to do her work.

About Sept. 1, 1947, the patient experienced dizziness and shortness of breath. After climbing several flights of stairs she would get very weak and dyspneic. However, she had no difficulty walking and working on level ground. This continued for several weeks before she was visited by her physician.

There was no history of exposure to chemicals and no family history of anemia. The patient had had a tonsillectomy and an adenoidectomy in childhood, the usual childhood diseases and an appendectomy in 1930. She had no disturbance in her vision or hearing. There was no sore tongue or bleeding from the oral cavity and no cough or hemoptysis. There was slight edema of the ankles at night. Palpitation was associated with the dyspnea. The appetite had been good, and she ate well balanced meals. There was no jaundice, constipation, hematemesis or melena. There had been no dysuria or other symptoms since the cystitis six months previously.

Physical examination revealed a well developed woman with lemon yellow skin. The eyes reacted to light and in accommodation. The fundoscopic examination revealed no hemorrhages. The arteriovenous ratio was normal. There were no palpable masses or tender areas in the neck. The chest was asthenic, with equal bilateral expansion. There were no rales on auscultation. The point of maximal impulse was in the fifth intercostal segment 16 cm. to the left of the midsternal line. There was a harsh systolic murmur loudest in Erb's area and transmitted into the pulmonary area and to the aorta area. There was no change in the sitting position. The pulse rate was 100, and the rhythm was regular. The blood pressure was: right arm, 110 systolic and 60 diastolic; left arm, 100 systolic and 60 diastolic; left leg, 170 systolic and 100 diastolic, and right leg, 160 systolic and 100 diastolic. The liver was palpable 2 cm. below the right costal margin in the midclavicular line. It was smooth and not tender. The spleen and kidneys were not palpable. The pelvic examination revealed no abnormalities.

The hemogram revealed 910,000 red blood cells, hemoglobin 4.5 Gm. and a white blood cell count of 2,250. The urine was normal, chemically and microscopically. Gastric analysis revealed 14 per cent free hydrochloric acid and 28 per cent total acidity after histamine. Blood proteins were 7.6 mg. with albumin 3.6 mg. and globulin 4 mg. per hundred cubic centimeters. The nonprotein nitrogen was 27 mg. per hundred cubic centimeters and icterus index 20.2 units. Stool examinations revealed no parasites or ova. Agglutinations were negative for paratyphoid organisms A and B, Bacterium abortus and typhoid H organisms. Proteus OX-19 and typhoid O organisms were present in agglutinations of 1:20 through 1:1,640 on two occasions. On later rechecks the results were negative. A blood culture was negative. The result of the tourniquet test was negative.

Roentgenographic studies of the chest revealed passive congestion of both lungs. The cardiac shadow was enlarged, with predominant left ventricular hypertrophy. There was no evidence of abnormalities of the great blood vessels or of disease of the thoracic cage. Views of the pelvis showed no pathologic bone or joint conditions. Studies of the gastrointestinal tract by means of the barium sulfate meal revealed no evidence of filling defect or deformity of the esophagus or stomach. There was a small diverticulum and a slightly larger one of the third portion of the duodenum. There was no gastric retention at six hours. At twenty-four hours the head of the barium sulfate meal was in the rectum. A barium sulfate enema showed no evidence of filling defect or deformity of the colon at this examination.

Intravenous pyelograms showed the left kidney to be larger than the right. There was a calcified body seen opposite the first lumbar vertebra. It was in the region of an upper minor calyx. The dye filled the right kidney normally. There was a possible defect between the upper minor calyx and the middle major calyx on the left. Both ureters filled normally. There was no evidence of defect of the bladder.

A retrograde pyelogram of the left kidney showed no evidence of filling defect or deformity of the renal calices, pelvis or ureter.

An electrocardiogram revealed an elevated P wave in leads 1, 2 and 3. The R wave in lead 1 and the S wave in lead 2 were large and the S waves small in leads 2 and 3. The QRS axis was plus 90 degrees. The T wave was elevated in leads 1 and 2 and low in lead 3 with an axis of plus 45 degrees. The ventricular gradient was plus 70 degrees. The impression was: slight right axis deviation of the QRS complex, but there was no evidence of ischemia.

A sternal marrow biopsy revealed hypercellular marrow. The fat spaces were not completely obliterated, but in proportion to the cellular element they did not occupy more than one fourth or one fifth of the volume of the marrow. The predominant cells were in the erythrogenic line, and most of these appeared to be erythroblasts. On one side of this stage in the development, the more immature cells appeared reticuloendothelial in character (some of which appeared characteristic of megaloblasts), while on the other extreme further progress in maturation eventuating in normoblasts was noted. The cells in the granulocytic series were rather sharply reduced in number. Megakaryocytes were present but not numerous.

The patient showed signs of acute left ventricular failure and was temporarily digitalized. Transfusions were continued, and the blood cell count showed improvement. An abscess developed on the buttocks, which caused a septic temperature for about three weeks. During this time there was not an increase in the white blood cell count. Penicillin was given for about three weeks.

On Sept. 24, 1947, the patient suddenly started to bleed from needle wounds, the sternal marrow biopsy wound, gastrointestinal tract, the gluteal abscess and the mucous membranes of the mouth.

Transfusions were continued, but the bleeding became severer. On September 26 the bleeding was so severe that it was feared the patient would shortly bleed to death. The bleeding time was several hours. Toluidine blue, 132 mg., was given intravenously. The bleeding ceased dramatically, and bleeding time was down to eight minutes. The following morning the bleeding time was seventeen minutes. At this time 68 mg. of toluidine blue was given intravenously. Thirty minutes later the bleeding time was four minutes. Transfusions were continued, but all of the bleeding had ceased. After about ten days the wounds started to granulate and heal.

The fragility test revealed: control, beginning hemolysis at 0.44 and complete at 0.30; the patient, beginning hemolysis at 0.46 and complete at 0.34. The reticulocyte count was 1 per cent on September 24 and 5 per cent on October 10.

The improvement continued. She was given reticulogen, 1 cc. daily beginning September 27. The reticulocytes were 5 per cent. An epinephrine test (Doan) was done, and there was no change whatsoever in any of the cellular elements. She was discharged from the hospital and has maintained a completely normal blood cell count since then.

Case 3.—A 24 year old white woman entered the hospital complaining of progressive weakness and fatigue of three months' duration. She had a low grade afternoon fever of one month's duration. Palpitation and dyspnea occurred on exercise. Small petechial hemorrhages had developed on the legs a few weeks prior to hospitalization. She had always bruised easily. The menses always had been scanty, but for the past two months they were profuse.

The past history was noncontributory, and the system review revealed no abnormalities.

Physical examination revealed a slender asthenic pale woman. There were numerous petechiae on the lower extremities, with a definite gravitational distribution. The pupils reacted to light and in accommodation. There were numerous fresh petechial hemorrhages in the retina. The ears were normal. The mucous membranes of the mouth contained many small petechiae. The dentition was normal. The chest was asthenic, and there were no rales in the lungs. The heart was midline, and the blood pressure was 104 systolic and 70 diastolic. There were no murmurs. The pulse rate was 110. The liver was smooth and palpable 2 cm. below the right costal margin. The spleen was smooth, hard and palpable 8 cm. below the left costal margin. A few small distinct nontender lymph nodes were palpable in the right axilla and left groin.

A diagnosis of subleukemic lymphatic leukemia was made, and general supportive treatment was started.

She was given a total of nine transfusions, first at weekly intervals and more frequently later. She continued a progressive downhill course.

On October 30 the petechiae became more pronounced on the legs. A decided increase in the heparin-like activity of the blood was found in the titrations, with the method of Allen. Toluidine blue was given in an attempt to stop the petechiae (2.5 mg. per kilogram of body weight was given the first day and 1 mg. per kilogram the second day). There was no oozing at this time. The platelet count was 23,000. No transfusions were given for two weeks. It was noticed that no new petechiae developed for one week. After this time new ones formed.

On Nov. 12, 1947, oozing from the mouth started and the patient vomited blood. The hemogram revealed 8.5 Gm. hemoglobin, 2,760,000 erythrocytes, 6,700 leukocytes, 25 neutrophils, 10 lymphocytes and 65 lymphoblasts. The platelet count was between 23,000 and 35,000.

The patient was given 3 mg. per kilogram of body weight of toluidine blue, and within the hour the oozing and vomiting ceased. There was no appreciable effect on the bleeding time, which was decidedly prolonged. Three days later bleeding again developed, and the medication was repeated with dramatic cessation of the bleeding. A spiking fever developed during this time.

In spite of repeated transfusions she continued a rapid downhill course and died sixteen days after her final admission. After the four infusions of toluidine blue, the patient had no more petechiae. Prior to the use of the dye two hundred petechiae were counted in an area 3 cm. in diameter. These completely cleared for the last week of life.

Postmortem examination revealed numerous petechial hemorrhages on the surfaces of the heart, lungs and small intestines as well as in the medullary portion of the kidneys. The spleen measured 10 by 5 by 20 cm. The mesenteric nodes were enlarged.

Microscopic sections revealed congestion in both lungs. Observations of the bone marrow confirmed the diagnosis of lymphatic leukemia.

## COMMENT

There was little if any response to the use of the dye in case 1. Facilities for the titration of the patient's blood for the presence of heparin-like substances were not available, and the test was not done. Undoubtedly, if this had been done, it probably would have revealed no response.

In the second case, however, the response to the intravenous administration of the dye was dramatic. The patient was practically morbid from oozing from the mucous membranes of her mouth, bowel and petechial hemorrhages in the skin. There had been no response whatsoever with the transfusions. Even though it has been reported that the dye does not affect the bleeding time, it is interesting to note that the bleeding time on September 27 was seventeen minutes just prior to the second injection of the dye. One-half hour after the completion of the procedure it was four minutes. No transfusions were given during this time. Titrations were not done in this case.

In the third case, the blood was titrated for heparin-like activity and it was obvious that this was decidedly increased. Therefore, the use of toluidine blue was indicated to stop the petechiae and oral bleeding. It worked dramatically, and, since the effect lasted about three to four days, it was repeated. It kept this patient comfortable during the last few days of her life. However, even though petechiae of the skin and oozing of the mouth were not observed during the last week of her life, numerous petechiae were found on the viscera at death. The last injection of the dye was eleven days before death.

One interesting observation in the last 2 cases was the rather dramatic feeling of well-being experienced by these patients after the medication was given and the hemorrhages ceased. This was noticed not only by the patient, but by the nurses and the family.

The antiheparin drugs are a valuable adjunct to the treatment of petechial bleeding associated with thrombopenia in properly selected cases. First, it may be used in preparation for splenectomy in thrombopenic purpura; second, in certain instances of acute bone marrow suppression it may be lifesaving, and a third important use is in decreasing the amount of petechiae and oral bleeding in patients with leukemia, thereby making the last few weeks of their life more comfortable. Fourthly, toluidine blue may be used to stop the bleeding tendency in a patient who has been given too much heparin in the treatment of phenomena.

## SUMMARY AND CONCLUSION

Three cases are reported in which toluidine blue was used in an attempt to stop the petechial bleeding and oozing in cases of bleeding secondary to thrombopenia.

Proper selection of cases is of extreme importance in the use of this substance.

## ADDENDUM

Since this article was written we have had the opportunity to do toluidine blue filtrations on thirty purpuric states associated with thrombopenia. The result of the test has always been positive in leukemias in this series.

# THE JARISCH-HERXHEIMER PHENOMENON IN LATE SYPHILIS

## Probable Fatal Reactions to Penicillin

VIRGIL SCOTT, M.D.
RICHARD W. MAXWELL, M.D.
and
JOHN S. SKINNER, M.D.
St. Louis

Since the introduction of arsphenamine the Jarisch-Herxheimer reaction has been a much debated, frequently maligned and little understood phenomenon. In early syphilis, the reaction is characterized by fever with or without an intensification of accompanying visible lesions, the complete reaction occurring within the first twenty-four hours following the administration of an actively antitreponemal agent. In late syphilis fever also occurs, but the clinical manifestations are more varied both in symptoms and in severity depending, probably in large part, on the anatomic site of the lesion(s) and perhaps, on the numbers of Treponema pallidum present. With the advent of penicillin, attention has been refocused on the Jarisch-Herxheimer phenomenon, and alarming, although not fatal, reactions presumably of this type have been reported in neurosyphilis,[1] in cardiovascular syphilis[2] and in syphilitic primary optic atrophy.[3]

The purpose of the present report is to record fatalities in 2 patients with late syphilis occurring within the first few hours after the institution of penicillin therapy. The evidence in one patient, with a proved gumma of the brain, who died suddenly and unexpectedly fourteen hours after the initial injection of penicillin, offers convincing proof to us of the occurrence of a fatal Jarisch-Herxheimer reaction and as such represents the first thus far reported following administration of this agent. In the second patient, with an aortic aneurysm which ruptured forty-nine hours after the institution of penicillin therapy, the circumstances are perhaps less conclusive.

### REPORT OF CASES

Case 1.—F. S., a 21 year old white housewife, was admitted to the gynecologic service of the St. Louis City Hospital on Jan. 19, 1948, with presumed vomiting of pregnancy. The relevant history, as reconstructed later, dated to one year prior to the present admission, when she consulted the outpatient clinic of another hospital for prenatal care. A diagnosis of early latent syphilis was made, and between Jan. 14 and July 27, 1947, she received twenty injections of oxophenarsine hydrochloride and nineteen of a bismuth compound. On the latter date she was delivered of a living nonsyphilitic[4] infant. The serologic reaction for syphilis, positive before treatment, was negative at the time of delivery.[5] The patient lapsed from observation and received no further treatment for syphilis.

The complaints necessitating the present hospitalization dated to one month prior to entry and included anorexia, nausea, vomiting, frontal headache, unsteadiness in gait, insomnia, nervousness and moderate generalized weakness. For two weeks she had noted photophobia and some blurring of vision. The last menstrual period had occurred ten weeks before admission.

On physical examination the (rectal) temperature was 37.2 C. (99 F.) pulse rate 88 per minute, respiration rate 24 per minute and blood pressure 120 mm. of mercury systolic and 80 diastolic. The patient was an obese, mentally sluggish girl who made every effort to keep her eyes shaded during the examination. From time to time she had mild, generalized "shaking" or "twitching" episodes, which she attributed to the light sensitivity of her eyes. The general physical examination elicited no abnormality except for enlargement of the uterus. No definite neurologic abnormalities were recorded at the time of admission, although adequate examination of the eyes was difficult because of intense photophobia. The gait was unsteady, but there was no ataxia of any of the extremities when tested individually.

Laboratory studies included a normal red blood cell count, hemoglobin, total and differential white blood cell counts, and urine. The standard Kahn reaction of the blood serum was positive (not quantitatively titered) as was the reaction to the Kolmer complement fixation test on two examinations. Lumbar puncture performed on the fourth hospital day showed elevation of the initial pressure to 230 mm. of cerebrospinal fluid. Examination of the fluid showed 37 lymphocytes, total protein 75 mg. per hundred cubic centimeters, colloidal gold reaction 5554433211 and a positive Kolmer complement fixation reaction with 0.5 cc. of spinal fluid (titration not done).

*Hospital Course.*—On bed rest the vomiting decreased in frequency, but the patient's mental sluggishness and unsteady gait remained unchanged. Occasional "twitching" episodes, which were believed not to be convulsive in nature, continued. At times pupillary responses seemed retarded and speech was described as slurred, but whether these were real or due to variations in interpretation is not clear. One examiner described haziness of the optic disks without definite elevation, but other cranial nerve abnormalities were not detected. On the eleventh hospital day (the last day of life) hyperactive tendon reflexes (bilateral) were recorded, and Babinski and Hoffman signs were present on the left. At this time a presumptive diagnosis of neurorecurrence with acute syphilitic meningitis was made and penicillin was begun, 60,000 units of crystalline G sodium penicillin being injected intramuscularly every three hours. Unfortunately, only one temperature observation was made between the first injection of penicillin and death, but six hours after the start of treatment (eight hours before death) the rectal temperature was elevated to 38.1 C. (100.6 F.). It is significant that this was the only elevation in temperature recorded during the entire eleven days of hospital observation. Thirteen hours after the first injection of penicillin the patient had a generalized convulsion, and one hour later was found dead.

At autopsy[6] the important findings, except for an 8 cm. fetus contained in the uterine cavity, were limited to the central nervous system. The brain weighed 1,240 Gm. The leptomeninges and blood vessels appeared normal, but over the convexity of the left hemisphere the convolutions were flattened and the sulci narrow. No pressure cone was apparent at the base of the cerebellum. On coronal section a subcortical lesion measuring approximately 3 by 2 by 2 cm. was found at the juncture of the left temporal and parietal lobes. The lesion was firm and rubbery in consistency, the central portion being a homogeneous lemon yellow color with a thin, irregular surrounding zone of pink containing scattered tiny areas of fresh hemorrhage. The left lateral ventricle appeared flattened and shifted to the right.

On histologic examination the homogeneous central area represented necrosis with complete loss of normal brain architecture. Toward the outer margin several thrombosed blood

---

[3] Moore,[2c] p. 58.

[4] This was proved by subsequent follow-up (negative reaction to blood test at 10 and 17 weeks of age).

[5] The preceding information was confirmed by written abstract. The diagnosis of early latent syphilis was based presumably on the patient's age and the presence of syphilis in her husband to whom she had been married for about one year. The fact that seroreversal occurred is in keeping with short duration of infection.

[6] Autopsy was performed by Dr. Francis E. Pennington, Department of Pathology, St. Louis City Hospital.

vessels and scattered areas of recent hemorrhage were present. The surrounding zone was composed of chronic inflammatory tissue with a dense infiltration of mononuclear cells, intense engorgement of blood vessels and pronounced perivascular cuffing. In many areas polymorphonuclear leukocytes made up a considerable proportion of the cellular infiltration. Sections from other portions of the brain showed normal-appearing meninges, blood vessels and parenchyma.

CASE 2.—E. J., a 44 year old white male factory inspector, was admitted to the St. Louis City Hospital on Oct. 1, 1947. Because he was stuporous, the history was fragmentary, and even the onset of the present illness could not be accurately dated. For over a year and a half he had complained of chronic malaise and listlessness to the extent that he had felt unable to work. Nine months before admission he had injured his back in a fall downstairs. Shortly thereafter a chronic morning cough developed productive of 15 to 30 cc. of yellowish sputum, which on two occasions (two months and one week before entry) had contained small amounts of blood. For two months he had complained of pain low in the back, and anorexia, weight loss and irritability had been present for one month. During the two weeks preceding admission he had felt too ill to get out of bed, and for one week there had been chills and fever. Severe occipital headache developed three days prior to entry, and eight hours before admission he had complained of a stiff neck. Two hours later he lapsed into semicoma.

The information was obtained subsequently that he had had a genital lesion fifteen to twenty years previously and that three years ago a serologic test for syphilis elicited a positive reaction on routine examination, but antisyphilitic treatment had never been received.

On physical examination the temperature was 40.0 C. (104.0 F.), pulse rate 120 per minute, respiration rate 28 per minute and blood pressure 110 mm. of mercury systolic and 60 diastolic. The patient was comatose and obviously critically ill. There was no body rash and no petechiae were seen on the mucous membranes. The ocular fundi appeared normal. Signs of consolidation (decreased resonance, bronchial breath sounds, and increased voice transmission) were described over the upper lobe of the right lung. The heart was considered to be of normal size; a faint (grade I) systolic murmur was heard at the cardiac apex. There was slight clubbing of the fingers of both hands. On neurologic examination the neck was stiff and Kernig's sign was present.

Laboratory studies showed mild normocytic anemia, 24,000 white blood cells with 2 per cent juvenile forms, 4 per cent stabs and 82 per cent segmented polymorphonuclear leukocytes, 4 per cent lymphocytes and 1 per cent monocytes. The urine contained a trace of protein. The standard Kahn flocculation and qualitative Kolmer complement fixation reactions of the blood serum were positive. The cerebrospinal fluid was cloudy and contained 4,100 cells, all of which were polymorphonuclear leukocytes. Bacteria were not demonstrated on direct smear, and cultures of the spinal fluid and of the blood remained sterile. Sugar was reported absent from the spinal fluid.

*Hospital Course.*—A presumptive diagnosis of meningococcic meningitis was made, and antimicrobial therapy was instituted. Crystalline G sodium penicillin, 20,000 units, and streptomycin, 100 mg., were instilled into the lumbar sac at the time of the first puncture. Systemically, crystalline G penicillin, 50,000 units, was injected intramuscularly every three hours, and sodium sulfadiazine was administered subcutaneously in a total dosage of 15 Gm. during the first twenty-four hours. At the end of this time consciousness had been regained and the temperature had fallen to 38.5 C. (101.3 F.). The cerebrospinal fluid now contained 4,800 polymorphonuclear leukocytes, 34 mg of sugar per 100 cubic centimeters and again no bacteria on smear. Penicillin and sulfadiazine were continued parenterally, and recovery from his acute illness seemed well under way, when, forty-nine hours after admission, he suddenly vomited a large quantity of bright red blood and died.

At autopsy,[7] the important findings were related to the aorta, where two saccular aneurysms were found in the descending portion. The proximal aneurysm, 2 cm. in diameter, was adherent to and had ruptured into the esophagus. The distal aneurysm, measuring 6 by 5 cm., projected posteriorly against the thoracic vertebrae, but erosion of the vertebral bodies was not present. The remainder of the aorta from the base of the aortic valve to the bifurcation exhibited extensive linear wrinkling and scattered raised yellow plaques.

The incidental gross findings included fibrosis of the upper lobe of the right lung with dense adhesions obliterating the pleural cavity in this region. Over the vertex of the brain there was a thin layer of cloudy yellowish exudate which was sterile on postmortem culture. The stomach was distended with approximately 2,000 cc. of fresh blood; the remaining viscera were pale.

On microscopic examination, hemotoxylin and eosin stained sections of the aorta showed mild to moderate thickening of the intima and extensive destruction of the media with focal collections of mononuclear cells. The vasa vasorum were surrounded by nests of similar cells. Sections through the site of rupture showed necrosis of the aneurysmal wall and of all layers of the esophagus.

## COMMENT

In early syphilis, Herxheimer reactions are common, occurring in 59 per cent of one penicillin-treated series.[8] These invariably occur early, within the first twenty-four hours after the initial injection, and are neither serious nor a contraindication to continued treatment. When treatment has been initiated with the usual dosages, it is apparently an all or none phenomenon, since recurrences of the reaction are not observed.[9] In penicillin-treated late syphilis, neurosyphilis constitutes the chief hazard and Herxheimer reactions (clinical and/or febrile, but predominantly the latter) have been reported in as high as 75 per cent of patients with dementia paralytica.[10] From the clinical standpoint convulsions and acute mania constitute the two most alarming types of reaction thus far described. Convulsions, severe and prolonged, have been observed in 2 patients by Tucker and Robinson,[1a] and similar reactions were reported by Stokes and associates.[1b] Callaway and his co-workers[1c] have described acute maniacal episodes occurring shortly after the institution of penicillin, and we have observed two similar instances. To our knowledge no report has thus far appeared on the treatment of gumma of the brain with penicillin, although we have treated one such patient without the occurrence of the Jarisch-Herxheimer phenomenon.

In the first patient herein reported the evidence favoring a focal reaction at the site of the intracerebral gumma as the immediate cause of death seems so convincing as to be almost irrefutable. Present knowledge of the biology of syphilis lends support to the hypothesis that precocious tertiarism, as exemplified by this patient, would constitute a situation ideal for the development of an intense focal reaction following the administration of a potent antitreponemal agent such as penicillin. It is true that the patient was seriously ill and that there had been no favorable progress during the ten days of observation, but her condition had not been considered critical. Of crucial importance from the standpoint of substantiating the occurrence of a Herxheimer reaction was the elevation of body temperature to 38.1 C (100.6 F.) six hours after the first injection of 60,000 units of crystalline G sodium penicillin and eight hours prior to sudden death.

Unfortunately, objective criteria have not thus far been established for the histologic diagnosis of a Herxheimer reaction in late syphilis, although Sheldon and Heyman [11] have recently described acute changes, identified by serial biopsies, in the moist genital lesions of secondary syphilis accompanying Herxheimer reactions due to penicillin. The reported changes include engorgement of blood vessels, edema and infiltration with polymorphonuclear leukocytes. In our opinion similar changes are present in the zone of reaction surrounding the gumma in our own patient, and Sheldon,[12] after reviewing the sections, concurred.

In cardiovascular syphilis the occurrence of the Herxheimer reaction following penicillin (or any other antitreponemal agent) is less well documented than in neurosyphilis. Two series of penicillin-treated patients, both small, have thus far been reported in the literature. Russek and associates [13] described their experiences in 15 patients with cardiovascular syphilis, 4 of whom had aortic aneurysm and 11 "syphilitic aortitis." One patient with an aneurysm, who previously suffered angina only on effort, experienced intermittent substernal pain at rest on the third day of penicillin therapy (40,000 units every two hours). This subsided despite continuation of treatment. No reactions were described in the remaining 14 patients, although specific mention of fever is totally lacking. The authors' failure to define their criteria for the diagnosis of syphilitic aortitis, a notoriously difficult clinical diagnosis, in 11 patients also detracts from the value of the report.

In the second series Tucker and Farmer [14] treated 34 patients (25 with syphilitic aortic regurgitation, 9 with aortic aneurysm) with varying initial doses of penicillin, one group with small doses (500 to 3,000 units), the other with large (25,000 to 100,000 units). Five patients had febrile reactions (without regard to initial dosage) within the first sixteen hours of treatment, which the authors ascribed to concomitant symptomatic neurosyphilis rather than to aortic syphilis. Two patients with angina of long standing had attacks of usual frequency and severity during and subsequent to penicillin therapy.

On the other hand, three groups of observers have reported 4 patients in each of whom circumstantial evidence suggested the possible occurrence of a Herxheimer reaction. In one of Dolkhart and Schwemlein's [2b] 2 patients, the complicating factor of rheumatic heart disease was present. In this patient, who had previously had angina on effort, precordial pain developed at rest on the second day of penicillin therapy, followed by episodes of ventricular extrasystoles, and further penicillin was not administered. The second patient with tabetic neurosyphilis and syphilitic aortic regurgitation, while receiving penicillin for an intercurrent infection, experienced on the third day of treatment precordial pain, for the first time in six years, and penicillin was discontinued. Callaway [1c] has reported 1 patient with syphilitic aortic regurgitation who was thought to have ruptured an aortic cusp ten days following the completion of penicillin therapy, and Moore [2c] has described a striking postmortem finding in 1 patient with dementia paralytica and syphilitic aortitis who died, presumably of cardiac failure, on the fourth day of combined malaria and penicillin therapy. At autopsy extensive syphilitic aortitis was present, and each plaque contained a large fresh hemorrhage.

The evidence for considering these as cardiovascular Herxheimer reactions is admittedly flimsy, and in our own patient conclusive proof cannot be presented. Undoubtedly the aneurysms had been present for some time and, almost certainly, spontaneous rupture would not have been long delayed. Nonetheless, the background of untreated syphilis of many years' duration and, as demonstrated at autopsy, the advanced syphilitic involvement of the entire aorta including the two large saccular aneurysms would predispose, if a Herxheimer reaction occurred, to precisely the type of fatal outcome that resulted, i. e., rupture of an aneurysm. McDermott [15] in discussing cardiovascular Herxheimer reactions has recently pointed out that the pathologic processes, or at least the demonstrable numbers of T. pallidum, are quite different in the syphilitic aorta [16] as compared to certain types of neurosyphilis, e. g., the brain in untreated dementia paralytica. In the aorta spirochetes are demonstrable with great difficulty by histologic methods,[17] while in the brain they may be present in large numbers.

It is also true, however, that the pathogenesis of the Jarisch-Herxheimer reaction is poorly if at all understood, and that a definite relationship between T. pallidum and the reaction itself has not been established. Such a relationship, however, seems at least probable, but whether this will prove to be in terms of numbers of organisms present, activity of organisms (multiplying versus resting), or, on the other hand, is dependent on such host factors as immunity or hypersensitivity is completely unknown at present.

In our patient any febrile reaction coincident with a Herxheimer phenomenon was masked by the fever associated with the purulent meningitis. The time relation between the initial injection of penicillin and death is compatible, we believe, with therapeutic shock. Although the febrile component of the reaction in late syphilis has usually been completed by the end of thirty-six hours, to our knowledge no information exists as to the time relations of the focal reaction at the site of the lesions. That the tissue phase may be retarded in comparison with the febrile response seems not only possible but likely. That coincidental rupture of an aneurysm should occur at a time when recovery from meningitis was well under way and when the strain on the cardiovascular apparatus was probably

16. Except perhaps in so-called gummatous aortitis.

17. Indeed, Frazier and his co-authors (Hu, C. K.; Liu, Y.; Chen, K. D., and Frazier, C. N.: Isolation of Virulent Treponema Pallidum from Human Aorta Thirty-Two Hours After Death from Cardiovascular Syphilis, Am. J. Med. 1:301, 1946) reported the isolation of T. pallidum by animal inoculation from the human aorta for the first time in 1946.

lessening seems remote. However, the possibility that rupture was coincidental cannot be categorically denied.[18]

The prevention of Herxheimer reactions requires further study. Considering the many thousands of patients who have already been treated with penicillin, the number of reported serious reactions has been small indeed, and whether preventive measures should be routinely attempted is open to question. Certainly in gumma of the larynx and of the brain (when recognized), where Herxheimer reactions may be fatal, probably in dementia paralytica and in primary optic atrophy, and perhaps in cardiovascular syphilis, attempts at prevention should be considered. Since Herxheimer reactions in late syphilis have been described even when treatment has been initiated with small doses of penicillin,[19] preliminary injections of a bismuth compound would be the logical choice, for, although therapeutic shock has been described following the use of this drug,[20] relatively few are on record. In neurosyphilis Moore[21] has suggested the use of one or more preliminary induced paroxysms of fever (malaria, hypertherm) before administering penicillin.

### SUMMARY

Two instances of sudden death occurring in patients with late syphilis soon after the institution of penicillin therapy are reported. In one patient, with a gumma of the brain who died fourteen hours after the initial injection, collateral evidence supporting the occurrence of a Herxheimer reaction is conclusive, and that death occurred as a direct result seems certain. In the second patient with rupture of an aneurysm forty-nine hours after the institution of penicillin, the evidence in favor of a fatal Herxheimer reaction is suggestive.

---

[18] In fact, McDermott[15] has observed such a coincidence, a patient with a *dissecting* aneurysm which ruptured during convalescence from pneumococcic meningitis.

**Fluorine in Newburgh's Water Supply.**—In Newburgh, New York, about fifty-one pounds of sodium fluoride—a highly toxic chemical—are added daily to the public water supply. Dissolved in the three million gallons of water used daily for all purposes in Newburgh, this amounts to about one part per million or less of fluorine in the water. This practice has been in effect for three years and will continue for another seven. Far from feeling any apprehension, the 30,000 inhabitants of this city consider themselves exceptionally fortunate. They are participating in a scientifically controlled experiment demonstrating the ability of fluorine, in trace amounts, to reduce the incidence of the most common disease of civilized—dental caries. . . . The Newburgh experiment, together with several similar ones in . . . other cities in the United States and . . . Canada, represents the first attempt to prove the fluorine-dental caries relationship by direct experimental methods. For the first time fluorine is being *added* to waters normally nearly fluorine-free in an attempt to reproduce conditions observed in areas where the water naturally provides optimal amounts of this element. As a further check on the results obtained for each city participating in this experiment there is a control city—a nearby city comparable in all respects (water-supply, population groups, climatic conditions, economic status and common sources of food supply), except that its water supply is fluorine-free.—Ruth Woods, The Role of Fluorine in the Diet, *Borden's Review of Nutrition Research,* March 1948.

# SURVEY OF MEDICAL CARE AMONG THE UPPER MIDWEST INDIANS

W. F. BRAASCH, M.D.
B. J. BRANTON, M.D.
and
A. J. CHESLEY, M.D.
Rochester, Minn.

The American Medical Association was asked by the Honorable Julius A. Krug, Secretary of the Department of the Interior, to investigate the medical care of those who are wards of that department. The investigation was divided according to various geographic areas and was carried on by several groups of physicians. We constituted a committee (W. F. B., chairman) to investigate medical care among the Upper Midwest Indians.

### THE MEDICAL OFFICER

It is obvious that the fundamental factor in the medical care of the Indian is the medical staff. We were very much interested, therefore, in meeting agency physicians and noting the character of their professional work. While in many instances professional standards of medical officers in the Indian Service are not of the highest type, nevertheless, we gained the impression that they are doing a rather good job. We were impressed with their loyalty to the Indian Service, their interest in professional problems and their human interest in their patients. In fact, they must have some kind of missionery spirit in order to help them carry on their work, in view of all the difficulties and deficiencies with which they have to contend.

Inability to secure enough physicians to fill the agency needs is the chief cause of most deficiencies existing in medical care of the Indian. Although two or three physicians are needed in most agencies, only one has been available in recent years and in several areas there is none. In some agencies the medical officer has to work day and night without relief, to the detriment of his health, as well as of the character of his work. The work of the medical officers is divided into three main activities, namely, hospital, field and outpatient services. When only one physician is available, the field service naturally suffers most; in fact, it often becomes nonexistent. The field service furnishes a type of practice similar to that of the general practitioner when engaged in house calls and is an important function in giving good medical and sanitary care. In some agencies the field service is taken care of entirely by nurses who, of course, lack medical training. The outpatient work is of equal importance, but often it is hurried and slighted because of pressure of other duties. In many hospitals

---

This report embodies impressions gained in the course of the survey made by the committee, together with recommendations which are suggested for improvement of the service.

In the course of its investigation the committee was assisted locally by Dr. A. D. McCannel of Minot, N. D., Dr. J. F. Replogle of Lander, Wyo., and Dr. T. F. Riggs of Pierre, S. D.

Secretary and Executive Officer of the Minnesota State Board of Health (Dr. Chesley), former President of the Minnesota State Medical Association and Director of the Willmar Clinic (Dr. Branton) and recent member of the Board of Trustees of the American Medical Association (Dr. Braasch).

The agencies were visited in the following order: Turtle Mountain Agency [illegible] Fort Peck Agency at Poplar, Mont.; Fort Belknap [illegible]; Blackfeet Agency at Browning, Mont.; Holy [illegible] gency at St. Ignatius, Mont.; Crow Agency [illegible] River Agency at Fort Washackie, Wyo.; Sioux [illegible] S. D.; Pine Ridge Agency at Pine Ridge, [illegible] y at Rosebud, S. D. Subsequently, the followi[illegible] and South Dakota were visited: Cass Lake, Red Lake, White Earth, the *Indian Annex of the State Tuberculosis* Hospital at Walker and the Sisseton Agency Hospital at Sisseton, S. D.

there is no technician and the physician must do the laboratory work. There is insufficient financial recognition for loyalty and for superior work—an incentive which is necessary for the best type of medical service. An atmosphere of lack of permanency and of uncertainty pervades the agencies. Because of low salaries, overwork and inadequate facilities, many physicians have resigned. Considering the isolated communities and the lack of social advantages where the physicians live, the large amount of work they do and the handicaps they contend with, it is a wonder that any of them remain. A generous increase in salary would be required to recompense them for the sacrifices they are making.

The relation of the superintendent of the agency to the medical officer appears to be friendly and cooperative in most agencies. In fact, we gained the impression that most of the superintendents are men of excellent qualities and that they have unusual executive ability. Handicapped by a reduced budget, they seem to carry on with a remarkable degree of efficiency. In several agencies they have sacrificed much needed office help in order to provide enough money for the health activities of the agency. Although the superintendent is given the responsibility and the supervision of agency affairs, he usually leaves problems of health largely in the hands of the agency physician. However, it would be for the best interests of medical care if the direction of all medical activities, including those of the hospital and the nurses, were put in the hands of the medical officer so far as interests of over-all administration of the agency would permit. A physician naturally resents control in matters of health by a layman, even though it is largely on paper. Control of medical and hospital care would be an added inducement to the highest type of physician to enter the service. The added responsibility would stimulate him in his efforts to give the best medical service possible.

The situation at Fort Berthold, in North Dakota, is an extreme example of the lack of medical personnel in certain agencies. On this reservation are some 2,000 Indians. There is no physician and no field nurse. Medical care is given by one staff nurse in a small dilapidated hospital. The nearest doctor lives in a small village 28 miles away, and he is so overworked that he is unable to look after the Indians. In case of emergency, the patients are carried by automobile to the nearest government hospital, which is 125 miles away. It is evident that contract medical service is impossible in this area. The hospital and equipment, as well as the living conditions and salary, should be made so attractive that a competent resident physician could be secured.

### DIRECTION OF MEDICAL CARE

The question has been raised whether medical care of the Indians should continue under the supervision of the Bureau of Indian Affairs or whether some other control should be considered, such as the United States Public Health Service. In recent years the medical service has been under the guidance of Dr. Ralph B. Snavely, who was loaned by the United States Public Health Service for that purpose. Serving under Dr. Snavely are several physicians from the United States Public Health Service, who supervise regional medical care. Control of the agency medical officer and of the hospital and nursing staff is held in the Bureau of Indian Affairs. It is said that the United States Public Health Service will not continue the present system of supervision unless the entire field of medical care is placed under its control.

Such reorganization would bring up several questions: 1. Would it be expedient to have a governmental field, which is included in the Department of the Interior, directed by officials in an entirely different department? 2. Should the function of the United States Public Health Service be to carry on the duties of a general practice of medicine, which medical care of the Indians demands? Medical opinion definitely would not favor it.

To separate medical care from other activities of the Bureau of Indian Affairs would be difficult. It would be preferable to have the Bureau of Indian Affairs appoint a physician with experience in Indian medical problems, both as practitioner and as administrator, as over-all supervisor of medical care. It might be advisable to have the health budget in the Indian Service separate from the general budget. An advisory committee of physicians, recommended by some national group such as the American Medical Association, could be of great service in solution of medical problems.

### NURSING STAFF

The nursing staff of the Indian Service is divided into two categories, namely, the hospital nursing staff and the field nurses.

*Hospital Nursing Staff.*—The hospital nursing staff is adequate in most hospitals, and the type of nurses in the service is definitely above the average. One of the main reasons for this is the high standard set and the efficient surveys made by the central nursing authorities in Washington. Several years ago, the salaries of the nurses were placed at a level which attracted nurses into the Indian Service and increased the length of time they were willing to remain in it. With recent increase in financial demands on nurses, it will be necessary to increase the present level of salaries in order to hold the staff nurses. The efficiency of the supervising nurses in the various hospitals is very evident. The general care of the patients and the thoroughness and cleanliness which exist in practically every hospital must be a source of pride to the Indian Service. Living in isolated areas, with lack of social advantages, these nurses make a real sacrifice in the conduct of their duties.

*Field Nurse.*—The work of the field nurse in the far flung Indian areas is essential to the health of their wards; in fact, in some ways it is of greater importance than that of the physician himself. Dollar for dollar, returns from the efforts of a field nurse in the care of health are greater than any other factor. Owing to the current scarcity of nurses, the number of field nurses in the service is insufficient for the needs. The physical and professional difficulties presented by a field nurse's duties, plus the isolation and climatic rigors of many Indian territories, have made it very difficult to secure sufficient personnel. Possibly the most important function of the field nurse in the Indian Service is that of household and sanitary adviser. The main ingredients of a successful field nurse are a personality which will gain the confidence of the Indian and a good share of common sense and diplomacy. It is open to question whether the high educational standards demanded for certification as a public health nurse are essential to duties of this kind. The basic training of a good practical nurse is sufficient for the nursing care required. A woman with a lot of common sense and some nursing experience, and one who understands and likes to work among the Indians—these are the essential qualifications. Such a woman can be of tremendous help in the care of the Indian. While one would hesitate to recommend the now discarded "field matron," yet one would also hesitate to advocate the other extreme, namely, an inexperienced college-bred social worker. Rather than wait for a supply of public health nurses, with the high standards of education now demanded of them, it would seem that a determined effort should be made to get women of the type described. It would be very desirable if Indian girls could become interested in this field work and could be given training for it. Among many Indian women in isolated areas, they would command a confidence which would not be given to a white woman. With the increasing number of intelligent high school graduates among Indian girls, training of them should become increasingly possible.

An example of the folly of rigid insistence on the high educational standards of a public health nurse is a situation which exists at Hays, Mont. This is a small community in the midst of the Indians of the Fort Belknap Agency and is situated about 35 miles from agency headquarters. There are excellent buildings and other facilities for a public health nurse and for agency medical care. Because of the inability to secure a nurse with the required standards, however, a vacancy has existed in this area for several years. There is available a certain nurse who has had excellent nurse's training and experience and who is familiar with the situation at Hays and with the peculiarities of the Indian population. However, she lacks a few months of the special training which are officially demanded of public health nurses, and permission to employ this nurse has been refused by authorities in Washington. The situation in Hays is almost of an emergency nature, and a directive should be forthcoming immediately which would permit appointment of the nurse in question.

### HOSPITALS

Although the hospitals in the agencies visited were erected twenty-five years or more ago, most of them have been kept up fairly well, are in good condition and are still serviceable. Owing to excellent management and nursing supervision, some of these hospitals are models of efficiency and cleanliness. Several hospitals were in some respects inadequate and partial reconstruction was indicated. Adequate x-ray and laboratory equipment was found to be lacking in many hospitals, and several needed modern sterilizing apparatus. Adequate facilities should be provided as soon as possible.

It will be necessary to replace the old structure at Poplar, Mont., which serves as a hospital for the Indians at the Fort Peck Agency. It is an old dwelling house which was remodeled into a hospital about forty years ago and is most inadequate. It has been suggested that this Indian hospital be rebuilt in Wolf Point, which is a larger adjacent community and which has several local physicians. The residents of Wolf Point propose that this hospital be used by both the Indian and white population. Such combined use of facilities will be discussed more fully later.

Perhaps in several instances, consolidation of several small hospitals into one large hospital should be considered. The consolidated hospital should have an enlarged and well trained staff and scientific equipment. This might be feasible if the distances are not too great and if year-round transportation is possible; such favorable conditions exist in some areas of Montana, South Dakota and Minnesota.

### HOSPITAL AND MEDICAL CARE IN COMMON WITH THE WHITE POPULATION

Integration of the Indian with his white neighbors would be encouraged by having the same hospital and the services of the same doctor for persons of both races. For example, there is an excellent hospital at the Fort Belknap Agency, which is situated only a few miles from Harlem, Mont. This community has no hospital, and the citizens would like to employ the hospital facilities of the agency. Since vacancies in the hospital frequently are as high as 50 per cent, the economic advantages of permitting the citizens of Harlem to use the hospital are evident. The physician in Harlem could cooperate with the agency medical officer in caring for both the Indians and the local white citizens. A somewhat similar situation in Wolf Point, Mont., has been mentioned previously.

The attitude of the adjacent population, white and red, toward such cooperation, however, varies. For instance, the residents of Lander, Wyo., would not care particularly to avail themselves of use of the Indian hospital, as long as they have access to their own hospital. On the other hand, at the Rosebud Agency in South Dakota, the Indians do not care to have the white population use their hospital.

Where the Indians have sufficient income to pay their way, private care by local doctors should be encouraged. As an illustration, many Indians under supervision of the Wind River Agency have income from oil lands sufficient to defray medical expenses. There is also no reason why the self-supporting Indian should not pay the usual hospital rates in the modern hospital situated at the agency.

### CONTRACT PRACTICE

Medical care in areas where there are not enough Indians to warrant a full time agency physician is provided through contract with private physicians practicing in the adjacent territory. Contract medical care seems to work out well in some areas, such as Fort Totten, N. D.; Riverton, Wyo., and Cloquet, Minn., although it is far from ideal. In some areas, however, the contract physician practicing in an adjacent community has been inefficient and medical care has been unsatisfactory. In isolated areas where large numbers of Indians need service, full time medical officers with modern hospital and nursing facilities are still essential to adequate medical care.

In view of budgetary limitations, contract practice has met with rather unfortunate results in some areas. As an illustration, in the area of Mille Lacs, Minn., the contract with a local physician to give medical care to the Indians was discontinued recently because of budgetary reductions. The several hundred Indians residing there are without funds and are receiving their medical care from an overworked local physician as charity. The county authorities claim they have insufficient funds to enable them to provide care for the Indians in the area and, furthermore, deny their responsibility. According to the regulations of the Minnesota State Welfare Board, the state is not responsible either, and, as a result, the medical care of Indians in this area is neglected. It would seem that the state and county could assume responsibility for the health and welfare of these few Indians. The Indian Service and state authorities must get together on their mutual responsibility and come to some understanding.

In an endeavor to economize, and possibly with a view to shifting responsibility, the Indian Bureau has been considering, for some agencies, replacement of the services of the medical officer by contract practice. Such replacement is being considered for the Indian agency at Sisseton, S. D. An arrangement is contemplated whereby a local practitioner, who has had experience in care of Indians, will take over the hospital care of the 2,000 to 3,000 Indians residing at that agency. It was also suggested that the hospital be managed by a local institution which would look after the patients on a contract basis. Careful study of this situation was made by the members of this committee, and we are agreed that the medical officer in the agency is providing an excellent service among the Indians and that the hospital is exceptionally well managed. The medical officer also is active in the field and in outpatient work, as a contract physician could not be. The agency physician has accomplished all this in spite of the fact that the general budget of the agency has been reduced to such an extent that to give adequate medical care is difficult. This committee is agreed that replacement of the medical officer at the Sisseton Agency by a contract physician would be unwise and that the work of the hospital there should continue as at present.

### MEDICAL PROBLEMS

The medical problems of the agency physicians are largely those of the general practitioner. He has to know something about all fields of medicine. Most of the medical officers recognize their limitations and call for consultation in difficult or obscure medical conditions. If nearby consultation is not available, patients who require it are sent to medical centers or university hospitals. The medical officer, in most agencies, does not attempt other than simple surgical operations. A few full time specialists in the employ of the Indian Medical Service make the rounds of the various agencies and render excellent service. If more specialists were made available, the medical service would be improved.

Sanitary conditions affecting Indian life are definitely substandard. Sporadic attempts have been made in the past to improve these conditions, but no consistent program of adequate sanitation has been followed. Practical sanitary surveys, carried out by sanitary engineers, are urgently needed. As a result of lack of sanitary conditions, many of the diseases common to white men are rampant among the Indians and require redoubled efforts on the part of medical officers to control them.

*Tuberculosis.*—The incidence of tuberculosis among the Indians always has been much higher than among the adjacent white population. Although in recent years there has been some improvement, the incidence still is too high. Contrary to general belief, the higher incidence does not seem to be due to greater susceptibility on the part of the Indian, but to lack of preventive sanitary conditions, failure of early diagnosis and insufficient medical and nursing supervision before and after hospitalization. Most of these deficiencies result largely from inadequate numbers of medical and field nursing personnel. In areas where these services are adequately supervised by the state board of health, as in Minnesota, the statistical improvement has been startling. Another factor which is not generally appreciated is that the Indian will respond to sanatorium treatment for tuberculosis as rapidly as, if not more rapidly than, his white brethren. It would be preferable to have a sanatorium available in the state in which the Indian lives. It is difficult enough to convince the Indian of the necessity for sanatorium treatment when the hospital is located nearby. State controlled sanatoriums are available in Minnesota and North Dakota, for treatment of Indians with tuberculosis. For strategic and economic reasons, the Indian patient in Minnesota is cared for in a separate wing of the state sanatorium. Provisions are being made in Montana for an addition of this type to the state sanatorium. At present, however, patients with tuberculosis in Montana and Wyoming are sent to a distant sanatorium, such as that in Rapid City, S. D., or Tacoma, Wash. The Sioux Sanitarium at Rapid City is a model for efficiency and good medical care.

Early recognition of tuberculosis among the Indians has been hampered by inadequate medical and nursing personnel. It has been helped recently in some areas by mass roentgen examinations. Early diagnosis also may be made by the wide awake field nurse, who has been taught to be on the lookout for early signs. The same nurse also can persuade the Indian patient to enter a sanatorium, and she can insure his recovery by observation and counsel after his discharge.

*Venereal Disease.*—Venereal disease is a common ailment with which the medical officer has to contend. Although limited in some isolated agencies, it is of frequent occurrence in others. Recent developments offer a standardized method of treatment of venereal diseases. Agency physicians, so far as resources permit, employ this treatment with good results. It might be well, however, to have a consulting venereologist review and criticize the therapeutic methods employed. An efficient state board of health can be of great help in controlling venereal diseases in areas where the Indians come in contact with the white population.

*Trachoma.*—Trachoma formerly was a curse among the Indians and caused as much disability as tuberculosis. The old treatment was painful and at best palliative. Since the employment of sulfonamide drugs the infection has been brought under control and in some areas has been largely eliminated. In a few areas, chronic infection remains among the older Indians, but the difference, compared with conditions in former years, is almost unbelievable.

*Dysentery.*—Dysentery is a common condition among the Indians, particularly those living in the more isolated agencies. Indian children frequently have severe forms of intestinal disease, which in most cases can be ascribed to faulty diet. The diet of the Indian, in spite of instruction and warnings, generally remains inadequate. In some agencies great quantities of berries are eaten during the berry season, with subsequent intestinal complaints. In some areas where the water supply is inadequate, ditch water is used for drinking and cooking, and frequently severe dysentery results.

*Obstetrics.*—Today practically all Indian babies are delivered in agency hospitals. Only a few years ago, midwives or old Indian women attended at childbirth. As one can well imagine, the rate of mortality of both mother and child was exceptionally high. The Indians themselves have learned of the advantages of hospitalization and now eagerly seek it. The result has been a remarkable improvement in mortality rates; in fact, complications of childbirth are now exceptional.

*Obligation of States in Care of Indians.*—It would seem that some of the states which harbor an Indian population do not fully appreciate their responsibility relative to the health and welfare of their Indian citizens and have done little to assume their obligations. Minnesota has led the way in cooperating with the Indian agencies in the care of the state's Indian citizens. The board of health of Minnesota and the boards of health of some other states have been interested in the welfare of Indians for many years. As a result of the efforts of these boards, the health of Indians has improved a great deal, as statistics will show. An outstanding service rendered by boards of health in several states has been the care of Indians suffering from tuberculosis. With the aid of a corps of efficient trained field nurses, tuberculous patients have been brought to sanatoriums and have been kept under observation after their discharge. Keeping of an adequate record of all tuberculous patients is no small part of the service rendered.

State boards of health have been active in caring for the health of Indians in other ways, such as child hygiene, care of crippled or disabled children, control of infectious diseases, prenatal and postnatal care, instruction as to sanitary conditions and dietary teaching. A health survey of a group of Chippewa Indians assembled for the wild rice harvest was made by the board of health in Minnesota several years ago, and the various diseases found were cataloged.

A federal budgetary shortage which prohibits necessary treatment of the tuberculous Indian is a calamity. This was the case in the Minnesota Chippewa Agency, which had insufficient federal funds this year to pay the moderate per diem hospital rates at the state tuberculosis sanatorium. As a result of this deficiency, 28 patients with positive sputum were dismissed from the sanatorium to return to their families. Every one of these patients was a possible source of infection to the relatives with whom he came in contact. This situation demands immediate correction.

Efforts have been made to have the entire medical care of the Indians, both therapeutic and preventive, become the obligation of the state in which they dwell. This responsibility would create many difficulties and would require active cooperation with state and county medical societies. The financial burden would be no small item in some states and would have to be met by federal grants in aid. This committee believes that the states in which the Indians reside should assume major responsibility for preventive medical care among Indians. Whether state authorities are in a position to assume therapeutic medical care and all other phases of Indian welfare is open to question.

*The Displaced Indian.*—One of the problems involved in the care of the Indian is the supervision of Indians who have left the reservation and gone to adjacent cities in order to take advantage of the comparatively high wages paid for labor. Two examples of the accompanying problems exist, respectively, on the outskirts of Rapid City, S. D., and at Havre, Mont. In both communities the migratory Indians squatted on dump heaps and neglected areas and were living in most inadequate quarters and under unsanitary conditions. The problem confronting Rapid City is particularly serious in that there are some 2,500 indigent or semi-indigent Indians located in the midst of a community of 25,000 persons. Their living quarters usually consist of small shacks, with inadequate windows and with no screens to protect them. Others live in tents or in huts made of refuse sheet metal. In order to secure even such quarters, it is necessary for some to pay as high as $20 a month rent. Water, plumbing and sewage are not available. Outhouses are few and far between, and in one instance a family of Indians was forced to pay $3 a month rent for the use of one. Living in these circumstances, the colony is a constant menace to the city as a possible source of disease. A few of the younger Indian girls were quartered in several houses of ill fame, located in the middle of the colony, giving the whole community a most unsavory reputation.

The Bureau of Indian Affairs holds that an Indian who leaves the reservation to live in some other area is no longer subject to its supervision and belongs to the community in which he settles. It is manifestly impossible for communities as small as Rapid City or Havre to assume the entire burden of permanently supporting and otherwise looking after such a large group of refugees. Although wages have lured many of the Indians to these areas, pay often is inadequate for their needs. Much of the money earned is spent in alcoholic excess. The economic responsiblity for these Indians remains unadjusted. Similarly, responsibility for the care of the squatter Indian's health remains uncertain, and neither the city nor the state desires to assume the burden. The Indians now depend on the charitable care of physicians practicing in the community. The resident physician at the Sioux Sanitarium, who is already overburdened with his duties, also gives of his services. The Bureau of Indian Affairs could hardly be held responsible for the situation. Solution of the problem should be assumed by state and county welfare commissions.

## SOCIAL AND ECONOMIC FACTORS

A discussion of medical care among the Indians is impossible without consideration of the economic and sociologic problems involved. The American Medical Association repeatedly has called attention to the fact that, in the maintenance of good health, medical care cannot be considered alone, since sanitary living conditions and adequate food, warmth and clothing are of even greater importance. In fact, outside of emergency situations, medical care alone would not be worth much without aid and cooperation relative to these other factors. In view of existing social conditions among the Indians, it is easy to understand why the level of their health is no higher than it is today. The truth is that the living conditions of most of the Indians are deplorable, and unless they are improved the work of the doctor and the nurse who care for them will remain largely handicapped.

Chief among the factors to contend with is the type of dwelling in which the Indian lives. While it is true that some of the more prosperous Indians live in acceptable houses, in the majority of cases the Indian's dwelling is too small, poorly ventilated and often dirty. Often two or more families will crowd into one small room. Although sporadic attempts have been made in certain localities to build better dwellings, they have been allowed to deteriorate.

Another factor which handicaps medical care is deficiency in or lack of the sanitary conditions which civilization demands. There is great need of frequent sanitary inspection and continuous regulation.

The living conditions of the Indian play a large part in the high incidence of tuberculosis and other diseases. A determined effort should be made to improve these conditions and subsequently to supervise the use of facilities provided, so that the Indian will not fall back into his old ways of living. Similar recommendations have been made in the past, but, largely because of lack of congressional appropriations, such recommendations have not been carried out as thoroughly as they should be.

The health of the Indian is intimately associated with still other factors of his life, such as education and social and economic conditions. These factors increase in importance in areas where integration of the Indian with his white neighbors is possible. Integration has been the goal of federal administration since the days of Jefferson, but development toward it has proved to be slow and difficult. It has succeeded only if the Indian's educational and economic opportunities have been on a level somewhat similar to that of his white neighbors.

The practice of encouraging communitywide participation in health activities among the Indians themselves is increasing. Health councils have been established in some tribes, with excellent results. In fact, in one instance a salaried board of health, composed of Indians, initiated ordinances which were approved by the entire tribe, and, as a result, sanitary and other living condition were improved and preventive medical measures were adopted. This development should be encouraged and expanded.

*Education.*—Much progress is being made in the education of Indian children. There is an increasing tendency to teach Indian and white children in the same schools, under the supervision of the state. Present educational policies, however, do not lead to a practical educational development. For instance, inability to earn a living lowers the moral stamina of many Indians and permits them to subside into alcoholism and unsanitary habits. If the educational training provided consisted of training in business, a trade or some special form of labor, which would permit the Indians to earn a living, improvement in health and in social well-being would follow. Opportunity should be given to the young male Indian to learn how to become an accountant, a silversmith or a road builder, and some of the girls should be given practical nurse's training, which they could use in many ways. Economic independence would stimulate a desire to maintain a healthy home, under sanitary conditions, and to live up to the elementary rules of personal care.

Among the many factors which hamper economic and social progress of the Indian, the following are deserving of comment: alcoholism, drug habits, illegitimacy and inadequate social and sanitary supervision.

*Alcoholism.*—As has just been indicated, one of the menaces to the health of Indians is the unfortunate addiction to alcoholic excess which is common to the males among them, particularly those of the younger generation. The excessive use of alcohol is a menace to both physical and moral health and a serious obstacle to progress. Temptation to illegal use of liquor, and difficulties in procuring it, act as incentives to its use. The laws prohibiting the sale of alcoholic beverages to Indians are so easy of circumvention that they are worthless, and it would be much better to abolish them. An educational program, including audiovisual means of showing the havoc, both physical and moral, resulting from intoxication, would be helpful.

*Drug Habits.*—The drug most frequently used by the Indian is peyote ("mescal button") which is obtained from the tops of a small narcotic cactus grown in the Rio Grande section of the United States and in Mexico. It is eaten by the Indian tribes of the Southwest in religious ceremonials, for the sense of well-being which it induces and to promote trances and hallucinations. The use of peyote has been a problem among Indians for many years. It has gradually spread so as to involve many of the Indians in the Northwest. Unfortunately, the Indian Bureau permitted use of peyote among the Indians several years ago on the grounds that it was part of an Indian religious ceremony. We are informed by the Narcotics Bureau of the United States Treasury Department that peyote is not covered by the Harrison Narcotic Act but that its use is prohibited by law in some of the southwestern states. It is high time that the sale and possession of this drug be restricted by a national law. It is a habit-forming drug and acts on the nervous system as a stimulant and narcotic. The drug usually is taken prior to festival dances and causes excessive stimulation for several hours. The following day the addict is left in an exhausted condition and is incapable of physical exercise or labor.

*Illegitimacy.*—Unfortunately, the Indian does not regard illegitimacy in the same way that his white brethren have been accustomed to regard it. He seems to take it as a matter of course. When it assumes the proportions that prevail in some areas, it becomes a definite sociologic threat. In some areas the percentage of illegitimate births is as high as 60 per cent. Lack of care of the child in already overcrowded living quarters increases the incidence of disease and results in an increase in mortality rate.

*Inadequate Social and Sanitary Supervision.*—If, in the course of the Indian's educational years, special emphasis were laid on the value of improved social and sanitary conditions, undoubtedly the status of his health would be improved. Social and sanitary supervisors would be needed to insure continued observance of healthful practices in these fields.

*The Budget of the Indian Bureau.*—As we reviewed the budgets provided for the Bureau of Indian Affairs in recent years, we were impressed with the lack of consistency on the part of Congress in meeting its financial obligations to the Indian. Adequate provision for essential needs is the best economy in the long run. Appropriations for the Indian Bureau have been reduced by Congress in recent years, apparently for two reasons: (1) to reduce federal expenditures and (2) to eliminate federal responsibility for the Indian. Failure to increase the budget of the Indian Bureau according to current demands has worked havoc with many of its activities. In no department of the Indian Bureau has this inadequate budget been a greater handicap than in the field of medical care. Although eventual elimination of Indian care as a federal responsibility may be desirable, it should be brought about gradually over the years and in areas where circumstances would permit it. It cannot be affected abruptly without injury to the welfare of the Indian. If the American people were aware of the failure on the part of Congress to appropriate sufficient funds for the health of the Indians, a justified wave of criticism would sweep the country.

## RECOMMENDATIONS

1. There is urgent need for a substantial increase in the budget of the Indian Bureau to meet the recent rise in costs of living and of all supplies. Of the various activities under the bureau medical service probably has suffered most, and financial provision for adequate medical care must be made immediately.

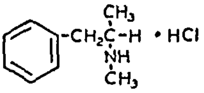
*The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.*

Austin Smith, M.D., *Secretary.*

**METHAMPHETAMINE HYDROCHLORIDE.**—"Desoxyn Hydrochloride"-Abbott.—"Norodin Hydrochloride"-Endo.—$C_{10}H_{15}N.HCl$.—M. W. 185.69.—*d*-Desoxyephedrine hydrochloride.—The hydrochloride of d-1-phenyl-2-methylaminopropane. When dried over sulfuric acid for eighteen hours, it contains not less than 79.5 per cent nor more than 80.8 per cent of anhydrous methamphetamine, corresponding to not less than 98.9 per cent of methamphetamine hydrochloride. The structural formula of methamphetamine hydrochloride may be represented as follows:



*Actions and Uses.*—The actions of methamphetamine hydrochloride are essentially similar to those of amphetamine sulfate; they differ only in degree. It appears that the central stimulant effects of methamphetamine may be slightly greater and the circulatory action slightly less than with amphetamine.

Methamphetamine hydrochloride may be used in the treatment of narcolepsy, in the control of oculogyric crises and various other manifestations of postencephalitic parkinsonism, as an adjunct in the treatment of alcoholism and in the treatment of certain depressive conditions, especially those characterized by apathy and psychomotor retardation.

Methamphetamine hydrochloride has also been used as an adjunct in the treatment of obesity. It depresses the motility of the gastrointestinal tract and allays the sensation of hunger. It may assist some persons to adhere to a strict dietary regimen. It may also assist those in whom overeating is a response to a depressive state.

The contraindications to the use of methamphetamine are the same as those for amphetamine, namely, hypertension and cardiovascular disease. The drug should not be administered within four hours before sleep is desired.

*Dosage.*—It is advisable to begin with a small dose of 2.5 mg. of the drug and, if necessary, to increase the dose by increments of 2.5 mg. until the optimal response is obtained.

*Tests and Standards.*—

Methamphetamine hydrochloride occurs as a fine, white, odorless, crystalline powder, possessing a bitter taste. It is unaffected by light. It is soluble in alcohol, chloroform and water, but insoluble in ether. Methamphetamine hydrochloride melts between 170 and 175 C. A 1 per cent aqueous solution is neutral or slightly acid to blue litmus paper and has a specific rotation, [a]25/D, not less than + 14° nor more than + 20°, when the measurement is made on a solution of the salt (previously dried for 18 hours over sulfuric acid), contained in a 200 mm. tube.

Dissolve 0.3 Gm. of methamphetamine hydrochloride, accurately weighed, in 10 cc. of water and add 1 drop of methyl red T.S. If the solution is pink, it is changed to yellow by the addition of not more than 1.5 cc. of fiftieth-normal sodium hydroxide. Dissolve 50 mg. of the salt in 40 cc. of water and add 1 cc. of diluted hydrochloric acid and 1 cc. of barium chloride T.S.: no turbidity develops within 10 minutes.

Prepare a 1 per cent aqueous solution of methamphetamine hydrochloride to be used for the following qualitative identification tests: it responds to the test for chloride. There is no change in color on the addition of ferric chloride T.S. *(difference from epinephrine and phenylephrine).* There is no detectable odor of carbylamine when a portion of the solution is heated to boiling with alcoholic potassium hydroxide T.S. and chloroform *(difference from amphetamine, phenylpropanolamine and Tuamine).* Mercuric potassium iodide T.S. yields an amorphous precipitate [illegible] *ephedrine, epinephrine, phenylephrine,* [illegible] *which yield no precipitate; and from* [illegible] *crystalline precipitate).* Mercuric bichloride T.S. gives a crystalline precipitate *(difference from amphetamine, ephedrine, phenylephrine, phenylpropanolamine and Tuamine, which give no precipitate; and from naphazoline, which gives an amorphous precipitate).* Sodium hypochlorite T.S. gives a precipitate *(difference from epinephrine and phenylephrine).* Phosphotungstic acid T.S. yields a white precipitate *(difference from epinephrine* [illegible] *which give no precipitate; and from naphazoline,* [illegible] *precipitate).* Iodine T.S. gives a brown [illegible] *erence from amphetamine, ephedrine, phenyl-* [illegible] *amine, which give a brown precipitate upon adding an excess of iodine T.S.; and* [illegible] *phenylephrine and phenylpropanolamine, which give* [illegible] acid T.S. gives no precipitate *(difference from* [illegible] A 1 per cent solution of picrolonic acid yields a precipitate *(difference from ephedrine, epinephrine, phenylephrine and phenylpropanolamine).* Platinic chloride T.S. gives a precipitate *(difference from amphetamine, ephedrine, epinephrine, phenylephrine, phenylpropanolamine, phenylpropylmethylamine and Tuamine).* A 1 per cent solution of phosphomolybdic acid yields a yellow precipitate *(difference from naphazoline, which yields a tan-colored precipitate; from epinephrine, which yields a brown-colored solution; and from phenylephrine, which does not react).* Picric acid T.S. gives a crystalline precipitate *(difference from amphetamine, ephedrine, epinephrine, phenylephrine, phenylpropanolamine and Tuamine, which give no precipitate; and from phenylpropylmethylamine, which gives an amorphous precipitate).*

Dry 0.25 Gm. of methamphetamine hydrochloride, accurately weighed, over sulfuric acid for 18 hours: the loss in weight does not exceed 0.2 per cent. Ignite 0.25 Gm. of methamphetamine hydrochloride, accurately weighed: the residue does not exceed 0.1 per cent.

Transfer about 50 mg. of methamphetamine hydrochloride, accurately weighed and previously dried over sulfuric acid for 18 hours, to a 100 cc. micro-Kjeldahl digestion flask and add 20 cc. of distilled water. Connect the apparatus and add 20 cc. of 50 per cent sodium hydroxide solution. Distil with a rapid current of steam until about 150 to 200 cc. of distillate has been collected in a beaker containing 20 cc. of fiftieth-normal sulfuric acid solution and 2 drops of methyl red T.S. Titrate the excess acid with fiftieth-normal sodium hydroxide to a salmon-pink endpoint. Each cc. of fiftieth-normal sulfuric acid solution is equivalent to 0.002985 Gm. of anhydrous methamphetamine base: the amount of methamphetamine base found is not less than 79.5 nor more than 80.5 per cent.

Transfer about 0.1 Gm. of methamphetamine hydrochloride, accurately weighed and previously dried over sulfuric acid for 18 hours, to a beaker, and determine the chlorine content by following the method outlined for the assay of Sodium Chloride-U.S.P. Each cc. of tenth-normal silver nitrate is equivalent to 0.003546 Gm. of chlorine: the chlorine content found is not less than 18.9 nor more than 19.2 per cent.

Abbott Laboratories, North Chicago, Ill.

**Elixir Desoxyn Hydrochloride:** 20 mg. per 30 cc., 500 cc. and 4,000 cc. bottles.

**Solution Desoxyn Hydrochloride:** 20 mg. per cc., 1 cc. ampuls.

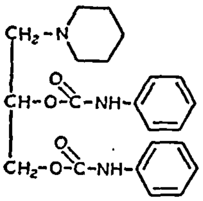
**Tablets Desoxyn Hydrochloride:** 2.5 mg. and 5.0 mg.

Endo Products, Inc., Richmond Hill 18, N. Y.

**Norodin Hydrochloride (Powder):** 1 Gm., 5 Gm. and 10 Gm. vials.

**Tablets Norodin Hydrochloride:** 2.5 mg. and 5 mg.

**DIPERODON.—Diothane-Merrell.**The *di*-phenylurethane of 1-piperidinopropane-2,3-diol.—Piperidinopropanediol *di*-phenylurthane.—$C_{22}H_{27}N_3O_4$.—M. W. 397.46.—Prepared by combining piperidine and glycerol monochlorohydrin in the presence of alkali, and reacting the piperidinopropanediol with phenyl *iso*-cyanate. The structural formula of diperodon may be represented as follows:



*Actions and Uses.*—See under Diperodon Hydrochloride (N.N.R. 1948, pp. 50-1).

*Dosage.*—See under Diperodon Hydrochloride (N.N.R. 1948, pp. 50-1).

*Tests and Standards.*—

Diperodon occurs as a fine, white, odorless, crystalline powder, which is nonvolatile and stable in air at ordinary room temperatures. The powder is tasteless but produces a slight sense of numbness. It is insoluble in cold water; slightly soluble in petroleum ether; and very soluble in acetone, alcohol, benzene, chloroform, ether and ethyl acetate. It melts between 78 and 82 C., and is very slowly decomposed by heating at 100 C. in air or in contact with water.

Dissolve about 0.9 Gm. of diperodon in 2 cc. of alcohol, add 2 cc. of diluted hydrochloric acid and dilute to 100 cc. with water. Mix the solution and test separate portions as follows: Add a few drops of mercuric potassium iodide T.S. to a 5 cc. portion of the solution: a yellowish-white precipitate forms. Add a few drops of gold chloride T.S. to a 5 cc. portion of the solution: a yellowish-orange precipitate forms *(distinction from butocaine and procaine, which yield brown precipitates, and from cocaine, dibocaine and Metycaine, which yield lemon-yellow precipitates; phenacaine yields a precipitate somewhat similar to that given by diperodon).* Add a few drops of potassium permanganate T.S. to a 5 cc. portion of the solution: a lasting precipitate, which turns from pink to brown within 1 minute, forms *(distinction from butacaine, cocaine, dibucaine, phenacaine and procaine, which do not immediately yield lasting precipitates).* To a 5 cc. portion of the solution add a few drops of diluted hydrochloric acid and a few drops of 10 per cent sodium nitrite solution followed by 3 cc. of a 2 per cent solution of β-naphthol in 10 per cent sodium hydroxide solution: a white precipitate changing to yellowish-white and finally to light orange forms *(distinction from butacaine and procaine, which yield red-brown precipitates).* Saturate 25 cc. of the solution with hydrogen sulfide: no precipitate or color develops.

Dissolve about 0.1 Gm. of diperodon in 1 cc. of sulfuric acid: the solution is colorless *(readily carbonizable substances).*

Ignite about 0.5 Gm. of diperodon, accurately weighed: the residue is not more than 0.2 per cent.

Dry about 0.5 Gm. of diperodon, accurately weighed, in a desiccator over phosphorus pentoxide: the loss in weight does not exceed 4 per cent.

Weigh, accurately, about 3 Gm. of diperodon and dissolve the sample in 10 cc. of ethyl alcohol previously neutralized to methyl red T.S. Add exactly 10 cc. of 0.1 *N* hydrochloric acid and 40 cc. of water. Warm gently, if necessary, to obtain a clear solution. Cool to room temperature, add 3 drops of methyl red T.S. and titrate to the bronze color of the indicator with 0.02 *N* sodium hydroxide. Each cc. of 0.1 *N* hydrochloric acid is equivalent to 0.03974 Gm of anhydrous diperodon: the amount of anhydrous diperodon found corresponds to not less than 94.0 nor more than 95.5 per cent of the sample weight.

The Wm. S. Merrell Company, Cincinnati

**Diothane Ointment with Oxyquinoline Benzoate:** Bulk and 28.4 Gm. tubes. Diothane 1 per cent and oxyquinoline benzoate 0.1 per cent, in an ointment base consisting of petrolatum, lanoline and mineral oil.

**OXYQUINOLINE BENZOATE.**—8-Hydroxyquinoline benzoate.—$C_9H_7NO.C_7H_6O_2$.—M. W. 267.27.—A compound consisting of a molecule of 8-hydroxyquinoline and a molecule of benzoic acid.

*Tests and Standards.—*

Oxyquinoline benzoate occurs as a yellowish-white, crystalline powder, possessing a characteristic odor and taste. It is slightly soluble in water; freely soluble in alcohol, benzene and ether; and soluble in vegetable and mineral oils. The *p*H of a saturated aqueous solution of oxyquinoline benzoate is about 4.0. It melts between 61 and 62 C.

Dissolve about 0.1 Gm. of oxyquinoline benzoate in 20 cc. of benzene and extract with two successive 5 cc. portions of sodium bicarbonate T.S. (collect the extracts for a later test). Wash the benzene layer with two portions of water and discard the washings. Dilute about 1 cc. of the benzene layer to 5 cc., with additional benzene. Add 5 cc. of water, 2 drops of ferric chloride T.S. and shake the mixture: an emerald-green color develops immediately in the water layer. Evaporate the remainder of the benzene solution in a stream of air: the melting point of the residue is 71-74 C. Acidify the sodium bicarbonate extract. Collect the precipitate on a filter, and wash and air-dry it: the product, which melts at 121-123 C., responds to tests for benzoic acid.

Ignite about 0.5 Gm. of oxyquinoline benzoate, accutately weighed: the residue is not more than 0.2 per cent.

Transfer about 0.3 Gm. of oxyquinoline benzoate to a suitable separatory funnel, add 25 cc. of benzene and 10 cc. of diluted hydrochloric acid; stopper the funnel and shake the mixture. Let the funnel stand until the layers separate cleanly and draw off the aqueous layer into a second separatory funnel. Rinse the benzene layer with two 5 cc. portions of water, combining the washings with the aqueous extract. To the second funnel add 25 cc. of benzene; stopper and shake vigorously. Let the funnel stand until the layers separate cleanly and draw off the aqueous layer into a third separatory funnel. Wash the benzene layer in the second funnel with two 5 cc. portions of water and combine them with the aqueous extract. Then: (A) Transfer the acid aqueous extract containing 8-hydroxyquinoline as the hydrochloride to a 500 cc. stoppered Erlenmeyer flask. Boil to remove benzene, cool to room temperature and add exactly 50 cc. of 0.1 *N* bromide-bromate solution. Stopper the flask, seal around the stopper with water and let the flask stand 15 minutes. Add water, bringing the volume to approximately 150 cc., and cool in an ice chest or ice water. Add 2 Gm. of potassium iodide or 10 cc. of potassium iodide T.S. Stopper the flask, let it stand for 5 minutes, and titrate the excess iodine with 0.1 *N* sodium thiosulfate solution. Each cc. of 0.1 *N* bromide-bromate is equivalent to 0.003627 Gm. of 8-hydroxyquinoline: the amount of 8-hydroxyquinoline found is not less than 51 nor more than 55 per cent. (B) Combine the benzene layer from the second separatory funnel with that in the first. Rinse the second funnel with 5 cc. of benzene followed by 10 cc. of water, combining both washings in the first separatory funnel. Add exactly 25 cc. of 0.1 *N* sodium hydroxide to the funnel containing the benzene and water washings, stopper and shake thoroughly. Allow the layers to separate cleanly and draw off the aqueous layer into a beaker. Wash the benzene in the funnel with two 5 cc. portions of water, combining the wash water with the aqueous layer in the beaker. Add 3 drops of phenolphthalein T.S., and back-titrate the excess sodium hydroxide with 0.1 *N* hydrochloric acid. Each cc. of the 0.1 *N* sodium hydroxide is equivalent to 0.01221 Gm. of benzoic acid: the amount of benzoic acid found is not less than 45 nor more than 47 per cent.

**ESTROGENIC SUBSTANCES (WATER INSOLUBLE)** (See New and Nonofficial Remedies 1948, p. 370).

The following dosage forms have been accepted:

Ayerst, McKenna & Harrison, Ltd., New York 16

**Solution Estrogenic Substances in Oil:** 10,000, 20,000 and 50,000 I. U. per cc. in corn oil, 10 cc. vials. Preserved with chlorobutanol 0.5 per cent.

Harrower Laboratory, Inc., Glendale, Calif.

**Solution Plestrin in Oil:** 10,000 I. U. and 25,000 I. U. per cc. in sesame oil, 1 cc. ampuls, 10 cc. and 30 cc. vials. Preserved with chlorobutanol 0.5 per cent.

U. S. trademark 233,746.

Smith-Dorsey Company, Inc., Lincoln, Neb.

**Aqueous Suspension Estrogenic Substances:** 20,000 I. U. per cc., 1 cc. ampuls and 10 cc. vials. Preserved with carbolic acid 0.5 per cent.

## REPORT OF THE COUNCIL

*The Council has authorized publication of the following report.*

Austin Smith, M.D., *Secretary.*

### ISOPENTAQUINE GENERIC NAME FOR (8-[4-ISOPROPYLAMINO-1-METHYLBUTYLAMINO]-6-METHOXYQUINOLINE)

The Council was requested by the Malaria Study Section of the U. S. Public Health Service to consider recognition of the generic term isopentaquine for the antimalarial compound known as Sn 13,274 (8-[4-isopropylamino-1-methylbutylamino]-6-methoxyquinoline). As a result of its deliberation, the Council voted to recognize the stated generic term. The Council calls attention to the fact that the drug wlil be available only as the oxalate salt, which should be designated as isopentaquine oxalate. In view of the fact that the base content of the salt is more uniform than the oxalate content, the labeling for any marketed product should bear a statement such as "Each tablet corresponds to ........ ........ isopentaquine base."

# Council on Physical Medicine

## REPORT OF THE COUNCIL

*The Council on Physical Medicine has authorized publication of the following report.*

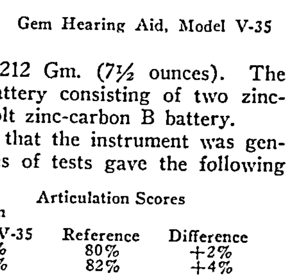
Howard A. Carter, *Secretary.*

### GEM HEARING AID, MODEL V-35 ACCEPTABLE

Manufacturer: The Gem Ear Phone Co., Inc., 80 Franklin St., New York 13.

The Gem Hearing Aid, Model V-35, is a so-called all in one wearable hearing aid. The ivory-colored plastic case contains microphone, amplifier and batteries. A metal clip is mounted in the center of the front through the microphone grill. A slender, flesh-tinted, plastic-covered receiver cord plugs into the center of the top of the case. Two wheel type controls, one for on-off and tone control, the other for volume control, are located at the two upper corners. The off position of the tone control is labeled and also can be identified by a flat segment of the wheel.

The outside dimensions of the case, exclusive of the clip, are 120 by 59 by 23 mm. (4¾ by 2⁵⁄₁₆ by ⅞ inches). The weight of the instrument, including batteries, receiver and cord, is 212 Gm. (7½ ounces). The instrument operates on an A battery consisting of two zinc-carbon dry cells and on a 22.5 volt zinc-carbon B battery.



Gem Hearing Aid, Model V-35

The Council obtained evidence that the instrument was generally well constructed. A series of tests gave the following results:

| Subject | Acoustic Gain | Articulation Scores<br>Gem Model V-35 | Reference | Difference |
|---|---|---|---|---|
| A | 45 db. | 82% | 80% | +2% |
| F | 52 db. | 86% | 82% | +4% |
| Average | | | | +3% |

The acoustic gain obtained by each subject was equal or nearly equal to the subject's own loss for speech. It is not expected that a hearing aid should make a subject's auditory acuity better than normal. The acoustic gain of this instrument was, therefore, at least 52 decibels, which exceeds the Council's minimum requirement. The articulation scores were roughly equal to those of the reference instrument, and both subjects reported the quality of the sound as good, clear and pleasant.

The Council on Physical Medicine voted to include the Gem Hearing Aid, Model V-35, in its list of accepted devices.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

SATURDAY, JANUARY 22, 1949

## OBITUARIES OF PHYSICIANS PUBLISHED IN 1948

During 1948 The Journal published the obituaries of 3,230 physicians, which was an increase of 190 over the number published in 1947. This number does not represent the total number of physicians who died during the year, as some reports were not received in time to be prepared for publication before the year ended.

The ages at the time of death of the 3,230 physicians ranged from 23 years to 100 years. Three died between the ages of 20 and 24, 43 between 25 and 29, 54 between 30 and 34, 63 between 35 and 39, 89 between 40 and 44, 138 between 45 and 49, 140 between 50 and 54, 237 between 55 and 59, 339 between 60 and 64, 471 between 65 and 69, 613 between 70 and 74, 475 between 75 and 79, 319 between 80 and 84, 161 between 85 and 89, 71 between 90 and 94 and 12 died after age 95. The average age at death in 1948 of 67.4 years continued the upward progression established by 65.3 years in 1945, 66.1 years in 1946 and 66.7 years in 1947. Except for the higher average age at death, there was no radical change in the age distribution of the decedents. In 1948 66 per cent of the decedents died at age 65 and over, whereas in 1947 64 per cent died in this age group.

The following analysis was based on the causes of death coded according to the "Manual of the International List of Causes of Death" (fifth revision). When more than one cause was stated in the obituary, primary and secondary causes of death were determined by the "Manual of Joint Causes of Death" (fourth edition). This method of classification is slightly different from that used in previous years.

Diseases of the heart accounted for 41 per cent of all deaths among physicians with a total of 1,338, of which 643 were caused by coronary occlusion, thrombosis and embolism, 149 by angina pectoris and other coronary diseases, 257 by valvular heart disease, myocarditis and endocarditis, 6 by rheumatic heart disease and 283 by other diseases of the heart.

Diseases of the nervous system caused 412 deaths. There were 390 deaths attributed to intracranial lesions of vascular origin; cerebral embolism, thrombosis and hemorrhage accounted for 381 of these deaths. Eleven deaths were due to Parkinson's disease and 5 to meningitis and diseases of the spinal cord. Cancer and other malignant tumors accounted for 348 deaths among physicians, while nonmalignant and unspecified tumors caused 10 deaths. There were 133 deaths due to cancer in the digestive organs, 43 in the respiratory system and 69 in the genitourinary system. Six deaths were caused by cancer of the skin and 4 by cancer of the brain. Diseases of the blood accounted for 41 deaths, of which 7 were due to anemia and 32 to leukemia. Arteriosclerosis caused 98 deaths, hypertension 13, aneurysm 22, other diseases of the arteries 14 and other diseases of the circulatory system 7 deaths.

Diseases of the respiratory system other than cancer and tuberculosis caused a total of 163 deaths among physicians, of which 121 were caused by bronchopneumonia, lobar pneumonia and pneumonia unspecified. Chronic bronchitis caused 3 deaths, asthma 3 and thrombosis, edema and congestion of the lungs 29 deaths. Tuberculosis of the respiratory system accounted for 22 deaths and tuberculosis of other systems and organs caused only 4 deaths. Fifty-seven physicians died of diabetes mellitus and 5 of acute rheumatic fever and chronic rheumatism.

Diseases of the digestive system other than cancer accounted for 114 deaths of which 35 were due to cirrhosis of the liver, 16 to ulcer of the stomach or duodenum, 11 to hernia and intestinal obstruction, 8 to diseases of the pancreas, 5 to peritonitis, 3 to appendicitis and 36 to other gastrointestinal conditions. Diseases of the genitourinary system other than cancer caused 135 deaths; various forms of nephritis 105, and diseases of the prostate 16.

Of the 45 deaths caused by miscellaneous diseases 5 were due to influenza, 5 to poliomyelitis and 11 to Hodgkin's disease.

Deaths resulting from accidents totaled 173; 50 were from motor vehicle accidents and 23 were from air transport accidents; 4 deaths were caused by drowning, 4 by conflagration and 11 by poisoning; 7 resulted from injury by firearms and 52 were due to falls.

Suicides accounted for 48 deaths; 13 by poisoning, 4 by hanging, 2 by cutting, 2 by jumping and 19 by firearms. Only 1 homicide was reported.

Senility was reported as the cause of 28 deaths and the causes of death of 63 physicians were not reported.

Contributing causes of death numbered 655. Arteriosclerosis was thus reported 114 times, coronary embolism, thrombosis and occlusion 40 times, other diseases of the heart 86, hypertension 78, pneumonia 54, nephritis and uremia 43 and intracranial lesions of vascular origin 41.

Twenty-three of the physicians whose obituaries were published were killed in action during World War II and 33 died while in military service. Seven were reported as having died while being transported as prisoners on a Japanese ship that was sunk, and 1 died in a prison camp in Japan. Three were killed in Germany, and 1 each at Iwo Jima, Normandy, Luzon, Okinawa, Guadalcanal, Admiralty Islands and Java. Of the deaths during military service 7 were caused by diseases of the heart, 10 by airplane accidents and 4 by motor vehicle accidents. Since the outbreak of World War II The Journal has recorded a total of 881 military deaths among physicians, of whom 313 were killed in action.

The average ages at death among physicians who died from some of the causes mentioned were: 74.3 years for pneumonia and influenza, 70.4 for intracranial lesions of vascular origin, 69.7 for nephritis, 65.6 for coronary occlusion, thrombosis and embolism, 67.4 for cancer and other malignant tumors, 64.5 for tuberculosis, 57.3 for accidents, 34.7 for physicians killed in action and 34.8 for those who died from other causes while in military service.

*Association Officers.*—The death of 1 former president of the American Medical Association was reported in 1948. Forty-two decedents had been members of the House of Delegates, 15 had been section officers, 1 had been a council member and 1 a chairman of a council. Among the deceased physicians there were 63 past presidents and 8 past secretaries of state medical associations and 284 past presidents, 1 president-elect and 46 past secretaries of county medical societies.

*Miscellaneous Positions.*—Two decedents had been university presidents, 4 had been presidents of medical colleges and 8 had been deans of medical schools. Two hundred and five had been professors and 108 teachers in medical schools. One of the deceased physicians had been a member of the National Board of Medical Examiners and 41 had served on state medical examining boards. One hundred and twenty-six were former members of the boards of education, 106 had served on boards of health, 269 had been health officers and 24 had been connected with state health departments. Among the decedents there had been 30 city councilmen, 6 aldermen, 23 legislators, 52 mayors, 64 coroners, 45 pharmacists and druggists, 7 dentists, 24 editors, 35 authors and 11 missionaries.

*Government Service.*—The obituaries published in 1948 showed that 2 of the decedents had served on the Mexican Border, 1 in the Boer War, 2 in the Philippine Insurrection, 54 in the Spanish-American War, 584 in World War I and 206 in World War II. Thirteen decedents had served with the armed forces of foreign countries. Two physicians had been Surgeon Generals, 72 had been in the Medical Corps of the United States Army and Navy and 29 had been in the Reserve Corps. Ten had served in the National Guard, 37 had been in the U. S. Public Health Service and 14 in the U. S. Public Health Service Reserve, 14 in the Indian Service and 34 with the Veterans Administration.

## THE CLINICAL TEACHING OF THE MEDICAL STUDENT

In the recent Inter-Professional Conference on Education for Professional Responsibility[1] modern clinical teaching of the medical student was discussed by James H. Means, Jackson professor of clinical medicine in the Harvard Medical School. In the medical schools of the United States teaching falls into the two main divisions of preclinical and clinical. The preclinical subjects—anatomy, physiology, biochemistry, pathology, bacteriology and immunology—are taught in the medical schools much as such subjects are taught in colleges generally. Thereafter begins the clinical training which is distinctive in medical education. The student now studies the patient in the flesh, and his interests change from the inanimate to the human animate. Means emphasizes that somehow there has developed in the student by this time a definite predilection of interest in organic disease. Usually the purely functional or psychogenic aspects of human behavior have not become of deep concern to him. "He still sees the patient as a collection of diseased organs rather than as a person in difficulty."

At the same conference John Romano,[2] professor of psychiatry in the University of Rochester School of Medicine and Dentistry, pointed out that the preclinical training of the medical student is more thorough in physics, chemistry and biology than in psychology, sociology, history and literature.

The teaching of clinical medicine differs from most other professional teaching in that three definite persons are concerned: teacher, pupil and patient. The teacher is responsible for conducting the teaching so that it benefits the patient as well as the student. Anything said within a patient's hearing "may be provocative of good or bad results, according to whether it is uttered skillfully or unskillfully." Means urges that "students should be made to understand all this before they ever come near a patient. They must be made to realize that to the patient they are doctors and that, as such, their utterances are important to him." The service of the student as clinical clerk and assistant in the care of patients is of great value in developing in him the professional conscience, clinical insight and understanding of disease. Means stresses also the great influence of the interviews and examinations of the patient by the clinical clerk in the development of the physician-patient relationship.

The actual responsibility placed on the student in his clinical training has steadily increased. As a rule patients are grateful to serve for the purposes of teaching and research. Teaching hospitals are preferred for internships and residencies. The clinical clerkship, actually an apprenticeship, as now conducted, is an effective introduction to the principles of practice. Means says: "As undergraduates, medical students are thirsty for knowledge. Also, they want to correlate it and make it practically useful to their patients. . . . Their approach to medicine is scholarly." As one encounters practicing physicians in graduate courses, however, one sees how their attitude toward professional work has deteriorated. One of the great problems of medical education, says Means, is how to make this scholarly attitude persist through life, how to insure that the physician and surgeon will continue professional without lapse into the merely vocational and commercial. Teachers of medicine, says Means, must set high examples in their own living. At this time mention only can be made of the increasing influence on maintenance of high standards in practice by the clinical and pathologic conferences by the staffs of our hospitals.

### MUSCULAR FATIGUE AND PEPTIC ULCER

Complete physical rest is often recommended by internists as a valuable adjunct in the management of peptic ulcer. This precept was derived primarily from clinical experiences, with little supporting experimental evidence. Lillehei and Wangensteen[1] of the Department of Surgery, University of Minnesota, studied the effects of moderate muscular fatigue on the incidence and severity of histamine-provoked peptic ulcer in dogs.

Fifteen dogs given continuous muscular activity and injections of histamine were compared with 13 not subjected to the activity. Among the 13 nonfatigued control dogs, 10 showed normal gastrointestinal tracts. Three (23 per cent) showed mild duodenal ulcers or erosions. Among the 15 fatigued dogs, only 4 showed normal gastrointestinal tracts. Eleven (73 per cent) showed relatively severe gastric, duodenal or jejunal ulcers or erosions. In 6 cases multiple ulcers were noted, two of which had perforated, causing the death of 1 dog. These results are in accord with the prevailing clinical belief.

In order to determine the mechanism of this deleterious action of muscular fatigue, the Minnesota surgeons studied the effect of exercise on gastric secretion. Two dogs with Heidenhain type pouches were repeatedly tested on days of rest and on days of a twenty to thirty minute run on the treadmill. In all cases the volume of gastric secretion was reduced as a result of this exercise. This was accompanied by a reduction in the percentage of both free and total hydrochloric acid.

This result suggests that the ulcer-abetting effect of muscular fatigue is not due to increased action of the gastric juice. It is presumably due to some change in the susceptibility of the gastrointestinal mucosa, conceivably a result of a reduction in local blood supply. This is in line with previous investigations by Baronofsky and Wangensteen,[2] who found that in dogs the vasoconstriction produced by epinephrine-in-beeswax injections increases the ulcer diathesis by creating anoxic areas in the gastrointestinal mucosa.

## Current Comment

### A NEW PULMONARY DISEASE ENTITY?

An unusual pulmonary disease occurred in Oklahoma in 1943 and was described by Cain and his co-workers in 1947.[1] An outbreak of this peculiar condition in Arkansas has now been described by Washburn, Tuohy and Davis,[2] who called the condition "cave sickness" because of the feature common to the outbreaks. In none of the occurrences was there an etiologic diagnosis established. A study was conducted on 21 white male patients who represented the greater part of the 25 persons engaged in a treasure hunt in an abandoned chalk mine in Southwestern Arkansas in which excavation was started Sept. 12, 1947. At intervals beginning with the fourth and ending with the thirteenth day of operations, all who had spent any time in the cave became ill in varying degrees of severity. Only persons who had entered the diggings were involved in the outbreak. The disease was a febrile illness with pulmonary manifestations. Onset was sudden after a short prodrome of coryza and malaise followed by chills and fever. The rest of the symptom complex was headache, in some cases with retro-orbital pain, nuchal tension, nervous irritability, slight cough, chest pain, loss of weight and certain general complaints. All signs were confined to the chest, where sonorous inspiratory and expiratory rales were heard early in the illness. These later became moist and sticky and disappeared after coughing. Clinical laboratory studies did not yield any positive results. Roentgenograms of the chest were spectacular and in keeping with the prostration of the patients. Distribution of lesions was uniform from top to bottom, of consistent size and shape without tendency to confluence, with absence of pleural reaction and freedom of involvement of the lymph nodes. The opinion is expressed that it was induced by a particulate entity spread almost entirely by hematogenous dissemination in a single shower. The disease was self limited to six or seven days, when the men were able to leave their beds, although residual weakness and a residual dyspnea persisted from September to February. Three degrees of severity were noted. The authors conclude that this is a new or, at least, a previously inadequately described disease. Careful future observations should disclose the etiologic basis now that the condition is well described. In such a case, convincing experimental tests would appear readily available should the cave contain the etiologic agent.

## Washington Letter

*(From a Special Correspondent)*

Jan. 17, 1949.

### Health and Medical Bills Descend on Congress

More than one thousand bills were introduced during the first week of Congress, although the Senate was in session only three days and the House four. More than a score of the new measures deal with public health and medical care issues, with chief interest focused on revived attempt to pass compulsory sickness insurance legislation. Senators Murray, Wagner, McGrath, Pepper, Chavez and Taylor and Representative Dingell joined in sponsoring the Eighty-First Congress version of so-called Murray-Wagner-Dingell legislation. The Senate bill is S. 5 and the House measure is known as H. R. 783. They are identical with S. 1320, on which protracted hearings were held in 1947 and 1948 by the Senate Committee on Labor and Public Welfare. A companion bill (H. R. 345) is sponsored by Representative Celler.

Other bills included among the record-setting number of measures introduced during the first week of the session were: H. R. 267 and H. R. 785, sponsored by Representatives Priest and Dolliver, respectively, on federal subsidization of public health units at local and community level; H. R. 62 and S. 102, sponsored by Representative Fulton and Senator Tobey, respectively, to stimulate research into the cause, prevention and treatment of multiple sclerosis; H. R. 184 and H. R. 782, sponsored by Representatives Harris and Dawson, respectively, for establishment of a new department to administer health, education and welfare activities of the federal government; S. Res. 16, introduced by Senato Langer, calling for a Congressional study of the feasibility of instituting compulsory hospitalization and surgical care insurance for the more than 2,000,000 persons in federal employ; H. R. 488, sponsored by Representative Keogh, which would give military credit to Army medical officers for service performed as civilian employees in Army hospitals, and H. R. 922, sponsored by Representative Rogers (Mass.), which provides for inclusion of barbiturates under the federal narcotic laws.

In addition, miscellaneous bills were introduced on amendment of the Hill-Burton hospital construction act, for construction of additional veterans' hospitals and authorizing the commissioning of x-ray technicians in the Army and Navy medical departments. Numerous identical bills were filed on establishment of a National Science Foundation, one of whose functions would be to coordinate research in the medical and biologic sciences. Sponsors of this type of legislation include Representatives Priest, Harris, Celler and Wolverton.

Senator Neely introduced a cancer bill (S. 68) under which the President would be requested to mobilize "an adequate number of the world's outstanding experts . . . in a supreme endeavor to discover means of curing and preventing cancer." It authorizes the appropriation of $100,000,000 for research, educational and control measures. Neely supported similar legislation when he was a member of the House in the Seventy-Ninth Congress. A companion bill is expected to be introduced in the House this year by Representative Andrew J. Biemiller.

### Statement by Congressional Sponsors of Sickness Insurance

In his opening message to Congress on January 5, President Truman called for "prepaid medical insurance without further delay." Accordingly, this segment of the administration's proposed social security program was selected for earliest introduction. A joint statement issued by Senators Murray, Wagner and McGrath and Representative Dingell made the following claims for the new insurance bills (S. 5 and H. R. 783):

Eighty-five per cent of the population will be covered, self-employed persons being included along with salaried workers and wage-earners. Those eligible for benefits will be entitled to medical and dental services from general practitioners and specialists, home nursing care, hospital care, laboratory service, roentgenograms, "expensive prescribed medicines," eye glasses and "special appliances." There will be free choice of physician or dentist and the right to change one's choice. Participation by physicians, dentists, nurses and hospitals will be optional. "These guarantees apply to organized groups of practitioners, clinics, consumer cooperatives and similar health service plans as well as to individuals. Every hospital that participates is guaranteed freedom from governmental supervision or control." The bills guarantee that payments to providers of professional services will be "fair and adequate." "The method of payment is to be decided by those practitioners who furnish the service." There will be "grass roots" administration of the program, with the medical profession to be represented on local citizens' groups which would frame administrative policies, within federal and state limitations.

### Report Issued on Hill-Burton Hospital Project Approvals

Sixty-one per cent of the 416 applications approved to date for hospital construction grants under the Hill-Burton Act are for publicly owned facilities, according to a recent report by U. S. Public Health Service. The remaining 39 per cent are for general hospitals sponsored by nongovernmental, nonprofit organizations. However, in terms of construction costs, the 162 private projects represent a total estimated outlay of $128,851,236, compared with $118,310,246 for the 254 that will be owned and operated as public institutions. The bed totals, respectively, are 10,207 and 10,758. In New England, 94.1 per cent of the project applications came from nonprofit organizations. On the other hand, in seven Southeastern states the approved applications submitted by nongovernmental organizations comprised only 27 per cent of the total.

### Dr. Houssay Will Conduct Research at National Institutes of Health

Dr. Bernardo A. Houssay of Argentina, 1947 Nobel Prize winner for physiology and medicine, has arrived in the United States to begin a three month period of fundamental research at the National Institutes of Health, Bethesda, Md. His investigations will be concerned with problems of endocrine gland regulation and balance and the relationship between the endocrines and metabolism.

## Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 7-8. Dr. Donald G. Anderson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Palmer House, Feb. 4-5. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

---

Alaska Territorial Medical Association, Juneau, March 3-5. Dr. William P. Blanton, Box 2569, Juneau, Secretary.

American Academy of General Practice, Cincinnati, Netherlands Plaza Hotel, March 7-9. Mr. Mac F. Cahal, 231 W. 47th St., Kansas City, Mo., Executive Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, Hotel Waldorf-Astoria, March 4. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, Palmer House, March 1-4. Dr. H. Kenneth Scatliff, 30 N. Michigan Ave., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

International Post-Graduate Medical Assembly of Southwest Texas, San Antonio, Jan. 25-27. Dr. John J. Hinchey, P. O. Box 2445, San Antonio, Secretary.

National Conference on Medical Service, Chicago, Palmer House, February 6. Dr. John S. Bouslog, 1612 Tremont Place, Denver Colo., Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Municipal Auditorium, March 7-10. Dr. W. D. Beacham, 1430 Tulane Ave., New Orleans, Secretary.

Southeastern Allergy Association, Durham, N. C., Washington-Duke Hotel, Jan. 22-23. Dr. Katharine B. MacInnis, 1515 Bull St., Columbia, S. C., Secretary.

# GOVERNMENT SERVICES

## ARMY

### RESEARCH AND DEVELOPMENT RESERVE GROUPS

The Department of the Army has established a program of particular interest to toxicologists and other scientists who hold reserve commissions and who are professionally engaged in teaching or research and development. The objectives of the program are to: (1) maintain the affiliation of scientists with the Organized Reserve Corps; (2) provide peacetime reserve assignments for these officers, enabling optimum use of their education, experience and skills; (3) furnish mobilization assignments which will fully use their talents, and (4) adequately prepare these officers for mobilization.

The Technical Services of the Department of the Army submit to these Research and Development Reserve Groups research problems and projects which pose an intellectual challenge to members of the group. Thus, the program provides members of each group with a type of training which is in keeping with their scientific and technical interests and competence rather than a traditional kind of training session in which scientists have little interest. To date, eighteen Research and Development Reserve Groups have been organized, and twelve are in process of organization. Others are in the initial stages of formation. Several of these groups have been formed in communities in which large universities, industrial research laboratories or private research foundations are located.

Provision is made to submit research projects of interest to chemists, physicists, engineers, geologists, geographers, psychologists, mathematicians, toxicologists, bacteriologists, serologists and scientists of other fields.

Reserve officers who are currently engaged in civilian research, college or university teaching, or industrial research or development, or who in the past have had specific research experience, are eligible to apply for assignment to an Organized Reserve Research and Development Group. A group may be organized in any locality where there are twenty or more qualified officer scientists who desire to participate in the program. A subgroup may be organized with ten qualified members. The program is under the general direction of the Research and Development Group, Logists Division, General Staff, U. S. Army. Inquiry about organization of an Organized Reserve Research and Development Group or about assignment to a group should be made of the Unit Instructor, O.R.C., or of the Senior Army Instructor, O.R.C., in the locality in which the officer resides.

### POSTGRADUATE INSTRUCTION

The following medical officers have been selected to attend postgraduate courses at the civilian institutions indicated: Col. Alexander C. Haff, radiology, Radiological Society of North America, San Francisco; Lieut. Col. Alonzo A. Towner, symposium on internal medicine, Mount Sinai Hospital, New York; Capt. Paul F. Guerin, pathology, Temple University Hospital, Philadelphia; Capt. Harold G. Page, general surgery, Mary Fletcher Hospital, Burlington, Vt.; First Lieutenants Sam A. Castro, intern training, Mercy Hospital, Chicago; Lowell H. Steen, intern training, Mercy Hospital, Chicago; Robert W. Morrissey, intern training, Iowa Lutheran Hospital, Des Moines; Frederick N. Talmers, intern training, City of Detroit Receiving Hospital, Detroit; Richard K. Blaisdell, intern training, Johns Hopkins Hospital, Baltimore; Albert J. Flacco, intern training, St. Luke's and Children's Medical Center, Philadelphia; Herschel J. Wells, medicine, Wayne County General Hospital, Eloise, Mich.; Arthur W. Samuelson, intern training, Grace New Haven Community Hospital, New Haven, Conn., and Barbara M. Knickerbocker, occupational therapy, National Foundation for Infantile Paralysis, Georgia Warm Springs Foundation, Warm Springs.

### COURSES IN PSYCHOTHERAPEUTIC MEDICINE

About seventy especially selected Army medical officers from a variety of medical installations recently completed a two weeks' course in psychotherapeutic medicine conducted at three Army general hospitals (Walter Reed, Washington, D. C.; Fitzsimmons, Denver, and Letterman, San Francisco). The instruction was led at these hospitals respectively by Drs. Benjamin H. Balser, New York; Jacob E. Finesinger, Boston, and Lawrence S. Kubie, New York, and each leader was assisted by a ten man team of civilian psychiatrists, psychologists and social workers.

The course, which was patterned on the initial 1946 experiment sponsored jointly by the Commonwealth Fund and the University of Minnesota, aimed at five specific goals: defining the patient-physician relationship, establishing the significance of a neurosis, pointing out the need for and methods of comprehensive diagnosis and therapy based on the interrelationship of emotional disturbance and somatic complaints, indicating the usefulness of the interview in both diagnosis and therapy and providing knowledge helpful in recognizing more malignant conditions. Throughout the course, major emphasis was placed on the art of medicine, which encompasses the whole man, as opposed to the current trend toward organ diagnosis and fractional therapy.

The students were uniformly enthusiastic about the course, which, while necessarily superficial, nevertheless "opened the door to an entirely new way of thinking." The response of the officers was so encouraging that plans are being made to repeat the course soon with chiefs of services and sections at Army hospitals as students.

### INSTITUTE OF PATHOLOGY

Brigadier W. L. Coke, Director General of Medical Services of the Canadian Army, visited the Army Institute of Pathology on November 26 and was guest of honor at a luncheon given by Brigadier General Raymond O. Dart, Director of the Army Institute of Pathology.

Dr. Maxwell L. Littman of the tropical medicine department of Tulane University School of Medicine, New Orleans, reported to the Army Institute of Pathology December 18 to act as consultant to the staff.

Dr. Webb Haymaker, chief, section on neuropathology, Army Institute of Pathology, recently addressed the staff of the Oliver General Hospital, Augusta, Ga., on the "Landry-Guillain-Barre Syndrome."

Dr. Walter G. Putschar of Charleston, W. Va., lectured at the Army Institute of Pathology Dec. 1, 1948, on "Pathology of the Intervertebral Disk."

### SAFETY RECORD CITED

The Department of the Army received the Award of Honor of the National Safety Council for distinguished service to safety. The award was presented to General Omar Bradley, Chief of Staff, in his office in the Pentagon in recognition of important reductions in the accidental injury rate in the Army's overseas operations during 1947. In the same ceremony, General Bradley presented the Army's Meritorious Civilian Service Award to Mr. Eliot V. Parker, Chief of the Army's Safety Branch, Personnel and Administration Division. Mr. Parker developed the worldwide Army safety program which affected great savings in money, man power and equipment and gave the Army a single unified attack against wasteful and unnecessary accidental suffering and loss.

# NAVY

## DR. SENSENICH'S LETTER TO YOUNG DOCTORS

More than 200 interns and residents now in training in various hospitals throughout the country have signified their interest in receiving a commission in the Naval Medical Corps Reserve. This interest is the result, the Navy's Bureau of Medicine and Surgery states, of a letter sent to all doctors under the age of 26 by the American Medical Association and signed by its President, Dr. Roscoe L. Sensenich. In the main, the letter offered information relative to a reserve commission in one of the medical departments of the armed services and advice to the young doctor in making a decision and a choice.

"The acceptance of a reserve commission," wrote Dr. Sensenich, "is evidence of willingness to serve and may be presented to the local board in support of your request for occupational deferment until the completion of your current year of internship or residency. Should you volunteer prior to being called for induction, you may make arrangements with the military services to postpone your active duty for a similar period."

## MEETING OF MEDICAL CONSULTANTS

The joint meeting of the honorary and reserve consultants to the Navy's Bureau of Medicine and Surgery January 28-29 at the Naval Medical Center, Bethesda, Md., will bring to Washington many of the nation's outstanding doctors. During the two day meeting, the honorary consultants will assist in formulating future policies for the Medical Department of the Navy, and the reserve consultants will advise and evaluate the present graduate medical training program as well as the present status of the Medical Corps Reserve. The honorary consultants, appointed by the Secretary of the Navy, act as an advisory board to the Surgeon General. The reserve consultants, appointed by the Surgeon General, many of whom are former Naval reserve officers, represent the specialties of the various American specialty boards and assist the Navy in establishing and maintaining a program which will provide training that meets the standards of these boards.

## FIRST ACTIVE DUTY

The following lieutenants (jg) in the medical corps reserve have been nominated for their first active duty to courses of instruction under the graduate medical training program, on completion of which they will serve on active duty: Frank M. Bryan, Fort Myers, Fla., to a residency in internal medicine at Bellevue Hospital, New York; John H. Heald, Billings, Mont., to a residency in radiology at Stanford University Hospital, San Francisco; Edward D. Loweecey, Pittsburgh, to a residency in internal medicine at the Naval Hospital, Philadelphia; Edward L. Mahon Jr., Kerrville, Texas, to a residency in surgery at the Naval Hospital, Bethesda, Md.; Francis P. Nash, East St. Louis, Ill., to a residency in surgery at St. John's Hospital, St. Louis; Charles O. Parker Jr., Waycross, Ga., to a residency in ophthalmology at the Naval Hospital, Bethesda, Md., and Robert H. Thompson, Dublin, Ga., to instruction in aviation medicine at the Naval School of Aviation Medicine and Research, Pensacola, Fla.

Lieutenants (jg) Donald H. McLean, New York, and Thayer A. Smith Jr., Short Hills, N. J., have been nominated for their first active duty in the medical corps reserve at the Naval Hospital of San Diego, Calif., and the Naval Shipyard, San Francisco, respectively.

## SAFETY CONFERENCE

The Navy held a regional safety conference at the Air Station, Jacksonville, Fla., January 11-13, at which the Bureau of Medicine and Surgery was represented, among others, by Captain H. K. Sessions of the Division of Preventive Medicine. At the dinner following the meeting, Captain Camille M. Shaar, M.C., commandant of the Naval Hospital, Jacksonville, gave the principal address.

## PERSONALS

The following reserve medical officers have been nominated for their first active duty: Lieutenants Haydon R. Duffy of Milwaukee to the Naval Hospital, Bremerton, Wash., and Robert J. Foley of Blair, Neb., to the Naval Hospital, Corpus Christi, Texas.

# PUBLIC HEALTH SERVICE

## DR. SZENT-GYÖRGYI A SPECIAL RESEARCH FELLOW

The U. S. Public Health Service announces that Dr. Albert Szent-Györgyi, winner of the 1937 Nobel prize for his isolation of vitamin C, and professor of biochemistry at the University of Budapest, is now working as a special research fellow at the National Institutes of Health, Bethesda, Md. He is conducting studies on muscle, the problem being the understanding of the contractile matter itself and then understanding the muscle cell as a whole. Dr. Szent-Györgyi, who was born in Budapest in 1893, received his medical degree from the University of Budapest and a Ph.D. from Cambridge University, England. While serving as professor of medical chemistry at the University of Szeged in Hungary, he made discoveries resulting in the isolation and identification of vitamin C and did fundamental work on biologic oxidation. He came to the United States in February 1948, after being awarded the special research fellowship.

## STUDY OF THE DONORA DISASTER

A comprehensive study of air pollution began January 10 at Donora, Pa., scene of a smog disaster where 20 persons recently died, the Surgeon General announced. Before a full scale study could be started, it was necessary to send a task force into the area to make preliminary observations and decide on a course of action. The task force study has been completed. The larger study will take in the entire Donora-Webster area in the Monongahela Valley. The study group will include 2 or more physicians, 4 nurses, a dentist, a medical technician, 6 engineers and 2 statisticians, all specialists in industrial hygiene.

The investigation is being made at the request of, and in cooperation with, the Pennsylvania State Department of Health, the Borough Council of Donora and the United Steelworkers, C. I. O. Public Health nurses will make a house to house canvass of Donora and nearby areas to obtain information from persons affected by the smog, and this will be followed by detailed medical and dental examinations. Air samplings taken throughout the area with equipment for detection of metallic and gaseous contaminants will be sent to Washington for further analysis in Public Health service laboratories. The group will conduct statistical studies of sickness and mortality records of the community to determine health trends and relative importance of specific causes of death. These data will be correlated with the clinical and environmental findings. The personnel will survey sanitation, housing and other related conditions which may have a bearing on health. Meteorologic observations will be made in cooperation with the United States Weather Bureau, and aerial photographs of the Monongahela Valley will be taken by the Coast Guard.

Dr. James G. Townsend, Chief of the Division of Industrial Hygiene, who organized the study, said that several months' work would be necessary to reach definite conclusions.

### MEETING ON FUNGUS ANTIGEN TESTS

The Division of Tuberculosis of the Public Health Service invites all physicians and other investigators interested in conducting skin test programs to attend a conference February 2-3 in Room 3523, Federal Security Building, Washington 25, D. C., on procedures for conducting fungus antigen tests to complement tuberculin tests. The meeting will seek to arrive at an understanding of definitions, interpretations and methods of recording results of the fungus antigen tests. The agenda include the following: selection of tuberculin and fungus antigens in appropriate doses, interpreting and recording reactions, interpreting roentgenograms and recording findings, designation of "residence" and permanent record forms.

### FEDERAL AID FOR CANCER INSTRUCTION

National Cancer Institute grants of $810,956 for cancer control projects and for cancer teaching in medical and dental schools were announced December 22 by the Federal Security Administrator. The grants which were approved by the Surgeon General of the U. S. Public Health Service had been recommended by the National Advisory Cancer Council, a group of cancer experts not connected with the government, who met in San Francisco to review the applications for grants. Eleven grants for cancer control, totaling $202,417, went to nonfederal institutions and agencies to support studies of cancer diagnostic tests, occupational cancer, tumor pathology, cancer teaching methods and other special control projects. Grants to continue cancer teaching of undergraduates went to twenty-three medical schools and nine dental schools and totaled $608,538.

### PILOT CANCER DETECTION CENTER

The pilot cancer detection center at Hot Springs, Ark., which is operated in conjunction with the Public Health Service Rapid Treatment Center for Venereal Disease, completed its first year of operation Nov. 13, 1948. During the first eight months of work of the center, 2 per cent of the 19,897 women patients with venereal disease who were examined had cancer, a rate uncovered slightly higher than average. The director of the cancer detection center at Hot Springs is Dr. Walter E. Doyle, who has been part time cancer control consultant for the Public Health Service. Dr. Doyle will also supervise the Arkansas project on cancer diagnostic tests.

## MISCELLANEOUS

### OAK RIDGE INSTITUTE OF NUCLEAR STUDIES

Scientists from many of the laboratories operated by the government began the new year in Oak Ridge, Tenn., learning how to use radioisotopes in research. They and other research workers, including two from foreign countries, make a class of thirty-two members who are taking the one month course in technics, the fifth of the series of cources offered by the Oak Ridge Institute of Nuclear Studies to train scientists in this new and important research tool. The institute, which is comprised of nineteen Southern universities, conducts a broad program of research through a contract with the Atomic Energy Commission. Priority for attendance at this particular course was given to representatives of government laboratories, as they are engaged in research work of great potential value to the country through a clear understanding of the cause and treatment of diseases, better crops, better use of natural resources and strengthening of the armed forces. Oak Ridge is the center of radioisotope production and training in the United States from which more than 4,600 shipments of radioisotopes have been made since August 1946, and where scientists from more than one hundred research organizations throughout the country have attended training courses offered by the Institute of Nuclear Studies.

### PHARMACOLOGISTS WANTED

The U. S. Civil Service Commission is accepting applications for pharmacologist positions which pay salaries ranging from $3,727 to $10,305 a year. The majority of the positions to be filled are in the Food and Drug Administration and the National Institutes of Health in Washington, D. C., and vicinity. To qualify, applicants must have had appropriate college study or a combination of such study and experience. In addition, they must have had from one to three years of professional experience in the fields of biochemistry, animal physiology, pharmacology or toxicology. Appropriate graduate study may be substituted for professional experience up to a maximum of two years of experience. No written test is required. Applications will be accepted in the U. S. Civil Service Commission, Washington 25, D. C., until further notice. Application forms may be secured at most first and second class post offices, from Civil Service regional offices or direct from the Commission's Washington office.

# Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

## CALIFORNIA

**Los Angeles Research Foundation.**—The Los Angeles County Medical Association Research Foundation was established January 19 as a nonprofit, charitable corporation organized "to foster studies on the cause, cure and prevention of disease, to gather and to administer funds for these purposes, to disseminate information and report to the public on problems of and progress in the conquest of disease." Its membership includes practically every person in the locality who is engaged in laboratory research in medical and allied fields. The professional members elect the board of directors, 80 per cent of whom must be members of the county medical association. Gifts of money have been offered to the association from time to time in the past to be used for medical research, but heretofore these could not be accepted since no mechanism existed by which they could be administered.

**Professional Conduct Committee.**—During the year 1948 the Professional Conduct Committee of the San Francisco County Medical Society considered 67 cases involving fee disputes (29), malpractice suits (16), questions on advertising (6), matters of unethical conduct (12), complaints against hospitals (2), complaints against undertaking firms (1) and one special investigation. In consideration of a membership of over 1,400, the committee feels that 67 such cases in a year was a small number. Most of the complaints received could have been avoided, the report said, by (1) amiable and frank relations with the patient, plus a willingness to sit down and discuss the issue at hand, and (2) knowledge of the Principles of Professional Conduct as set forth in the Constitution and By-Laws of the San Francisco County Medical Society, copies of which are available to all members of the society, on request.

## CONNECTICUT

**Yale Clinic to Assist Industry.**—The Yale Plan Clinic began early in January a new consultant service to assist industry evaluate losses resulting from alcoholism. It will assist in determining the extent of alcoholism within the company and will advise on existing problems of discipline, termination of employment, insurance and pension payments, labor-management relations and health services. The clinic will also recommend alternative possibilities for treatment of alcoholic addicts who show good indications of rehabilitation and will provide educational information. As evidence of the seriousness of the problem to industry, clinic officials pointed out that more than 50 per cent of the first 1,000 patients coming to the clinic were employed in industry. All branches of the Yale Plan Clinic, together with the National Committee for Education on Alcoholism, will participate in the new consultant service. Dr. George Lolli, medical director, and Raymond McCarthy, executive director of the Yale Plan Clinic, will be in charge of consultation, training and the rehabilitation services.

## DISTRICT OF COLUMBIA

**Director of Group Hospitalization Retires.**—Mr. E. J. Henryson retired in December as the first director of Group Hospitalization, Inc., a voluntary prepayment plan which serves the Washington area. He had held this position since 1934. One of his last major contributions to the voluntary prepayment movement was the counsel and assistance he provided when members of the medical profession established Medical Service of the District of Columbia as a medium through which they could offer the public their plan for voluntary prepayment of surgical care. The physicians' plan, which was first offered last April, is administered by Group Hospitalization, Inc.

## ILLINOIS

**Roentgen Survey in Evanston.**—More than 24,000 persons were given roentgen examinations in a recently completed survey in Evanston, conducted jointly by the city's health department, the Tuberculosis Institute of Chicago and Cook County and the Illinois State Department of Public Health. Three hundred and fifty-three cases of tuberculosis or suspect cases were found. Of those given roentgen examinations in the thirty-nine day program, 14,935 were women, among whom were found 394 cases of chest disorders other than tuberculosis and 759 cases indicating heart disease. About 29 per cent of persons given roentgen examinations were nonresidents and 96.6 per cent of persons who took part in the project were adults.

### Chicago

**Hektoen Institute.**—At the annual meeting of the Hektoen Institute for Medical Research of Cook County Hospital, the following persons were appointed as research associates on the staff: Drs. Ernst Loeffler, Bruno W. Volk, Fenton Schaffner, Joseph Silverstein and Jerome M. Swarts, all of Chicago.

**Personals.**—Dr. Arno B. Luckhardt, William Beaumont distinguished service professor of physiology at the University of Chicago, was elected 1947 Man of the Year by Phi Beta Pi, professional medical fraternity. The fraternity many years ago established the Arno B. Luckhardt lecture.——Dr. Hugh McCulloch, St. Louis, has been appointed medical director of the Council on Rheumatic Fever of the Chicago Heart Association and medical director of LaRabida Jackson Park Sanitarium.

**Research Fellowships Awarded.**—The University of Illinois Graduate College is offering ten one-year research fellowships in medicine, dentistry and pharmacy. Each carries a stipend of $1,800 a year for medical and dental graduates and $1,200 for pharmacy graduates with exemptions from tuition fees for all appointees. Registration in the graduate college for credit toward M.S. or Ph.D. degrees is required. Fellows are eligible for reappointment in competition with the new applicants. Candidates should indicate the field of research in which they are interested and submit transcripts of their scholastic credits, together with the names of three former science teachers as references. Appointments will be announced about March 1. The fellowship year begins on July 1 or September 1. Application blanks may be secured from the Secretary of the Graduate Committee, 1853 W. Polk Street, Chicago 12.

**Special Society Meetings.**—The Chicago Urological Society meeting January 27 at 8 p. m. in the Congress Hotel has invited the following speakers:

Marie Lehner, Chicago, Massive Unilateral Congenital Cystic Kidney: Case Report.
Geoffrey A. Fricker, Chicago, Hypernephroma with Solitary Metastases: Case Report.
Irwin T. Rieger, Chicago, Unusual Hematuria: Case Report.
Harold L. Briskin, Hines, Clinical Notes on Perirenal Air Injections.
Frederick J. Wahl, Chicago, Clear Cell Renal Carcinoma of Twenty-One Years' Duration: Implication of Endocrine Relationship to Growth.

——At the meeting of the Chicago Society of Internal Medicine January 24 at the Drake Hotel at 8 p. m. Drs. Paul S. Rhoads, Floyd A. Svec and Joseph H. Rohr, all of Chicago, have been invited to speak on "Laboratory and Clinical Observations on the Use of the New Sulfonamide Gantrosan," and Dr. Jerome R. Head, Chicago, on "Streptomycin in the Treatment of Pulmonary Tuberculosis." Dinner will be served in advance of both meetings.

## INDIANA

**Medicine in the 81st Congress.**—Dr. Joseph S. Lawrence, director of the Washington office of the American Medical Association, will address the Conference of County Medical Society Officers in the Claypool Hotel, Indianapolis, January 30, 12:30 p. m. on "What Medicine May Expect from the 81st Congress."

**Appoint Director of Child Guidance Clinic.**—Dr. John H. Waterman, associate professor of psychiatry at Indiana University School of Medicine, Bloomington-Indianapolis, is the director of the Child Guidance Clinic being established at the University Medical Center under the sponsorship of the Indianapolis Junior League. It was to begin operation November 1, and will be available to the entire state on the same basis of administration as are other clinics devoted to child patients at the Medical Center. Dr. Waterman, a graduate of the University of Nebraska College of Medicine, Omaha, 1933, has been with the Houston (Tex.) Child Guidance Clinic on the faculty of the University of Texas and Baylor University, Houston. The League will contribute $15,000 annually to the support of the clinic.

## KANSAS

**Summary Course in Radiology.**—A postgraduate course in radiology has been arranged for February 7-9 by the University of Kansas faculty in cooperation with the Kansas Medical Society and the Kansas State Board of Health as part of its program of postgraduate study. The course attempts to present a brief summary in the field of radiology in diagnosis and treatment. It is open to all doctors of medicine and surgery in Kansas and adjacent states. Among the instructors are Drs. James F. Brailsford, Birmingham, England; John P. Caffey, New York; Edwin C. Ernst, Columbia, Mo.; David S. Dann, Kenneth C.

Holweg, William M. Kitchen, Ira H. Lockwood, Louis A. Scarpellino, Arthur B. Smith and John W. Walker, all of Kansas City, Mo. A fee of $20 will be charged to all except interns and residents on identification by their hospital superintendents. Communications should be addressed to Extension Program in Medicine, University of Kansas Medical Center, Kansas City 3.

**Mid-Winter Clinical Conference.**—The Sedgwick County Medical Society and the Veterans Administration Hospital of Wichita are holding a Mid-Winter Clinical Conference February 18-19. Among the speakers will be Drs. Oscar T. Clagett, Mayo Clinic, Rochester, Minn., and Paul S. Rhoads, professor of surgery, Northwestern University Medical School, Chicago. Local clinics will be held each day [illegible] matology, obstetrics and gynecology, [illegible] and radiology. Drs. Mahlon H. Delp, F[illegible] C. Bartlett, Wichita, will hold clinics in medicine and surgery respectively on Friday. There will also be a symposium on "Duodenal Ulcer" by Drs. Thomas J. Rankin, Philip Cooper and James B. Fisher, all of Wichita. On Saturday a clinical pathologic conference by the local men will be held.

## LOUISIANA

**State Surgical Association.**—On November 11 the Surgical Association of Louisiana was formed to foster surgical knowledge, to aid surgical advances and to promote ethical standards among members. Dr. Urban Maes, New Orleans, presented a paper on "A Plea for Better Clinical Diagnosis in the Field of Medicine." Officers elected were Drs. C. Grenes Cole, New Orleans, president, and Henry G. Butker, New Orleans, secretary.

**Psychiatrist to Give the Matas Lecture.**—The annual Rudolph Matas Lecture will be given January 27 at 8 p. m. in the Hutchinson Auditorium, Tulane University of Louisiana School of Medicine, New Orleans, by Dr. William C. Menninger, clinical director of the Menninger Foundation in Topeka, Kan. His subject will be "Everyday Need for Psychiatry." All members of the medical profession are invited. The Matas Lecture was named in honor of Dr. Rudolph Matas, professor emeritus of surgery at Tulane and renowned vascular surgeon. It is sponsored by the Beta Iota Chapter of Nu Sigma Nu.

## MINNESOTA

**Minnesota Health Days.**—The Minnesota State Medical Association and the state department of health have conducted health days in every section of the state during 1948. Beginning last February people in all counties assembled to discuss health needs of their communities. Governor Youngdahl has addressed the evening meetings; morning group discussions studied health problems of local concern; health motion pictures were shown and local or county health councils have been organized.

**War Memorial Blood Bank.**—The Minneapolis War Memorial Blood Bank began to serve the community as a central blood bank on December 1. It will replace the small blood banks that have operated independently of one another at most of the Minneapolis hospitals since 1940. The Hennepin County Medical Society has been attempting to work out a plan since 1942. Part of the personnel of the bank will be full time employees; at least six of the medical technologists will be rotated from the various hospital laboratories in four to six week periods.

## NEW YORK

**University Appointments.**—Dr. Merel H. Harmel, Philadelphia, has been appointed associate professor of anesthesiology at Albany Medical College and attending anesthetist at Albany Hospital. He is a graduate of Johns Hopkins Medical School, Baltimore, 1943. Dr. Charles M. Landmesser, a graduate of Cornell University School of Medicine, New York, 1942, has been appointed instructor in anesthesiology and assistant attending anesthetist at the hospital.

**Postgraduate Lectures.**—Postgraduate lectures have been arranged by the Medical Society of the State of New York and the New York State Department of Health as follows: The Medical Board of James T. Mather Memorial Hospital will hear Dr. Charles A. R. Connor, New York, speak on "Rheumatic Fever" at the hospital in Port Jefferson, February 24, 11:30 a. m. The Suffolk County Medical Society meeting at the Patchogue Hotel, Patchogue, Long Island, January 26 at 7 p. m., will hear Dr. Gaylord W. Graves, New York, speak on "Problems of Practice in the First Year of Life."

**Rotation of Interns.**—A rotation plan whereby interns and resident physicians of large hospitals visit smaller hospitals within their region is proving beneficial, according to Dr. Paul Lembcke, associate director of the Council of Rochester Regional Hospitals. The plan was set up two years ago as a five year experiment through a Harkness Fund grant. In addition to the rotation plan, specific needs which the council found were: (1) a program of clinical conferences, (2) a full day session in postgraduate work for nurses, (3) regular notices of medical meetings throughout the territory sent to all physicians, (4) organization of hospital medical staffs and (5) a unified system of recording hospital services and professional activities.

### New York City

**Diphtheria at a Record Low Rate.**—The City of New York Department of Health in its 1948 report listed a record low figure for diphtheria—153 cases and 6 deaths. No major outbreaks of communicable diseases occurred in the city during the year. An increase of 735 newly reported cases of tuberculosis was noted in the first forty-eight weeks of 1948. The report states that more than one half of the persons who died in New York City in 1948 were more than 62 years old.

**Dr. Bernecker Joins Medical Center Staff.**—Dr. Edward M. Bernecker, recently retired commissioner of hospitals in New York City, has been appointed administrator of hospital services with the New York University-Bellevue Medical Center. He will be responsible for the administration of the University Hospital, the Institute of Rehabilitation and various university clinics and for the coordination of clinical programs for teaching in other hospitals associated with the Medical Center. Dr. Bernecker is a graduate of Hahnemann Medical College, Chicago, 1915.

**Dr. Rubin Named Chairman of Medical Staff.**—Dr. Eli H. Rubin, attending physician at Morrisania City Hospital in the Bronx, has been named director of medicine and chairman of the medical staff at Seton Hospital in the Bronx, a 500 bed tuberculosis institution taken over by the city last May 1. Seton Hospital had been operated as a voluntary institution since 1895, and had planned to close because of the heavy financial burden. Acquisition for operation by the department of hospitals was authorized because all cases there were city charges. Dr. Allen Kane is medical director.

**Diabetes Detection Experiment.**—An experiment in diabetes detection was recently conducted on Staten Island by the Richmond County Medical Society in cooperation with the Staten Island Pharmaceutical Association. It made a simple urinalysis available free to all persons in neighborhoods served by local drug stores. Eighty-seven of ninety drug stores on Staten Island and physician members of the medical society participated in the experiment. If the Staten Island experiment shows that the neighborhood approach yields satisfactory results, the experiment, it is reported, will be repeated throughout the country by the National Association of Retail Druggists.

**Personals.**—Dr. Jacob M. Ravid has been appointed pathologist and director of laboratories at the St. Clare's Hospital. Dr. Ravid was formerly pathologist at the Izrael-Zion Hospital, Brooklyn, a position which he has held for fourteen years. He is a graduate of Johns Hopkins University School of Medicine, Baltimore, 1926.——Dr. William H. Shehadi, formerly director of radiology at Mount Vernon Hospital, has accepted the position of professor of radiology and director of the department at Now York Polyclinic Medical School and Hospital.——Dr. Lloyd H. Gaston became director of St. Luke's Hospital January 1, succeeding Dr. Claude W. Munger, who retired because of ill health. Dr. Gaston has been acting director since July 1, 1948.——Dr. George B. J. Glass, New York, has been appointed assistant clinical professor of medicine at the New York University Medical College, Flower and Fifth Avenue Hospitals. Dr. Glass is a graduate of Uniwersytet Jozefa Pilsudskiego, Warsaw, 1927.

**Outpatient Cost Rises 100 Per Cent in Decade.**—The Hospital Council of Greater New York reports that, despite a reduction in outpatient service in recent years, its expense increased more than 100 per cent between 1937 and 1947 in the forty-nine voluntary general hospitals. The report indicated that from 1937 to 1947 the cost of a visit rose 160 per cent, from $1.09 to $2.82. The council made suggestions to improve the service, including saving of time and energy by patients and hospital staff, a supervised nursery for children in conjunction with clinics for adults to facilitate attendance of mothers with young children and reorganization of the outpatient department so that a patient could be examined by several specialists on a first visit. While the cost of such a visit might be more than the average cost of the present type of clinic visit, a more complete service for the community at a lower total cost to the public would be provided, the report said. A change of working hours to correspond to the needs of working persons, coordination of inpatient and outpatient services and the establishment of unit record systems were also suggested.

## OHIO

**Dr. Gall Appointed Professor of Pathology.**—Dr. Edward A. Gall, a graduate of Tulane University of Louisiana School of Medicine, New Orleans, 1931, has been appointed Mary M. Emery professor of pathology and head of that department in the College of Medicine, University of Cincinnati, and director of the department of pathology at Cincinnati General Hospital. In 1941 he became pathologist at Bethesda Hospital in Cincinnati and assistant professor of pathology in the university's college of medicine. Dr. Gall was district physician at the Boston Dispensary and assistant in medicine at Tufts Medical College, Boston, 1933 to 1935; resident in pathology, 1935 to 1937, and assistant pathologist, 1937 to 1940, at Massachusetts General Hospital, Boston; instructor in pathology first at Tufts Medical School, 1935 to 1940, and at the Harvard Medical School, Boston, 1940 to 1941. For the four years beginning 1942, he was on active duty with the Army Medical Corps. He succeeds the late Dr. Richard S. Austin.

## PENNSYLVANIA

**Recommend Changes in Department of Health.**—Recommendations aimed at improving, enlarging and strengthening the State Department of Health were submitted this month to Governor James H. Duff, jointly by the Medical Society of the State of Pennsylvania, the Pennsylvania Psychiatric Society and the Public Charities Association of Pennsylvania. Included in the proposals were the elevation of the Secretary of Health to a major secretariate and the transfer of the Bureau of Mental Health from the Department of Welfare to the Department of Health. It was further recommended that state-owned hospitals and the financial assistance program for state-aided general hospitals also be transferred from the Department of Welfare to the Department of Health.

### Philadelphia

**Lecture on Psychosurgery.**—The fifth Phi Delta Epsilon Lecture was given by Dr. Walter Freeman, Washington, D. C., on "Recent Developments of Psychosurgery" January 6 at Jefferson Medical College.

**Course in Diseases of the Chest.**—The Council on Postgraduate Medical Education of the American College of Chest Physicians and the Laennec Society of Philadelphia will present a postgraduate course in diseases of the chest to be held at Warwick Hotel, Philadelphia, February 28-March 5. It is open to all physicians, although registration will be limited. The tuition fee is $50. Application may be made to the executive offices of the American College of Chest Physicians, 500 North Dearborn Street, Chicago 10.

**Personals.**—Phyllis A. Bott, Ph.D., has been appointed professor of physiological chemistry and chairman of the department at the Women's Medical College of Pennsylvania, Philadelphia. Dr. Bott, a graduate of the University of Wisconsin, became associate professor in 1941, and in 1946 became chairman of the department.——Dr. W. Edward Chamberlain, professor of radiology at Temple University School of Medicine, Philadelphia, gave the annual Phi Chi Lecture at the University of Texas Medical Branch December 1. Dr. Chamberlain discussed medical practices in Poland and Finland, in which countries he recently surveyed medical conditions.——Dr. Wilbur E. Burnett, head of the department of surgery at Temple University School of Medicine, was the honor guest speaker at a postgraduate course in general surgery presented by the Dallas (Texas) Southern Clinical Society.——Dr. D. Franklin Milam was appointed national director of the Planned Parenthood Federation of America January 3. Dr. Milam, a graduate of the University of Chicago Medical School, 1924, has for twenty-five years been a member of the field medical staff of the International Health Division of the Rockefeller Foundation. He succeeds D. Kenneth Rose, who resigned in November.

## TENNESSEE

**Tennessee Adopts Voluntary Prepayment Plan.**—A voluntary program of medical care and insurance has been adopted by the Tennessee State Medical Association. Benefits will be payable whether service is rendered in the home, office or hospital. The schedule of benefits is to be accepted as full payment by participating physicians of services to individuals earning less than $2,400 and to families whose incomes do not exceed $3,600. For persons in the higher income brackets the schedule of benefits allows the doctor to charge more if he wishes. All licensed insurance companies in Tennessee will be encouraged to participate in the program.

## TEXAS

**Appoint Dean of Postgraduate School.**—Dr. Randolph L. Clark Jr., director of the M.D. Anderson Hospital for Cancer Research, Houston, has been appointed dean of the University of Texas Postgraduate School of Medicine, a division of the Texas Medical Center, Houston. Courses offered at first will be short term refresher training courses for graduates.

**Post-Graduate Medical Assembly.**—The International Post-Graduate Medical Assembly of Southwest Texas will be held at the Municipal Auditorium in San Antonio January 25-27. Guest speakers include:

E. Vincent Askey, Los Angeles, Unusual Problems Encountered in the Diagnosis and Treatment of Acute Appendicitis.
Clarke H. Barnacle, Denver, Psychiatry for Senescence.
Sidney Farber, Boston, Treatment of Cancer.
Ray F. Farquharson, Toronto, Canada, Diseases of the Biliary Tract.
Ralph A. Fenton, Portland, Ore., Dangers and Defenses of our Airways.
Jack S. Guyton, Baltimore, Combined Liver Biopsy and Liver Function Study.
C. Howard Hatcher, Chicago, Results of Treatment of Sarcoma Primary in Bone.
Leon O. Jacobson, Chicago, Chemotherapy in the Treatment of Neoplastic and Allied Disorders.
Robert R. Linton, Boston, Thrombophlebitis, Phlebothrombosis, Pulmonary Embolism—Its Cause, Prevention and Treatment.
Jesus Lozoya S., México, D. F., Acute Abdomen in Children.
James L. Poppen, Boston, Surgical Treatment of Hypertension.
Jonathan E. Rhoads, Philadelphia, Pre- and Postoperative Care of Surgical Patients.
James C. Sargent, Milwaukee, Bladder Cancer: Its Recognition and Management.
Paul C. Swenson, Philadelphia, Chest Lesions Easily Confused with or Resembling Neoplasm.
Richard W. Te Linde, Baltimore, Functional Uterine Bleeding.

There will also be luncheons with question and answer periods, a clinical-pathologic conference and scientific and commercial exhibits. A registration fee of $20 covers both meetings and luncheons. For military personnel the fee is $10.

## VIRGINIA

**Dr. Lehman Honored.**—Faculty colleagues and former students recently honored Dr. Edwin P. Lehman of the University of Virginia Medical College, Richmond, in recognition of his twenty years of service as professor of surgery and gyncology. A dinner and reception were given, and Dr. Lehman held a clinic in the medical school amphitheater for former students and residents. Dr. Lehman is now president of the American Cancer Society and the Southern Surgical Association. Dr. Evarts A. Graham, professor of surgery at Washington University, under whom Dr. Lehman worked in St. Louis before coming to the University of Virginia, gave a lecture on cancer of the lungs.

## GENERAL

**Damon Runyon Fund's First Fellowship Award.**—The Damon Runyon Cancer Memorial Fund's first two fellowships in clinical research have been awarded to Dr. Genevieve M. Bader, New York, and Dr. Richard B. Eisenberg, Philadelphia. Thirty-three additional fellows will be named under the $150,000 grant by the fund to the American Cancer Society for administration.

**Director of Mental Hospital Inspection.**—Dr. Ralph M. Chambers, former superintendent of Taunton State Hospital in Massachusetts, has been appointed Director of Inspection and Rating of Mental Hospitals in the United States, a procedure for better standards set up by the American Psychiatric Association. The new system of inspection was made possible by grants from the Psychiatric Foundation.

**Foundation Spends Over $17,000,000 During 1948.**—More than $17,000,000, it is estimated, was spent by the National Foundation for Infantile Paralysis assisting families and communities in the 1948 epidemic; of this more than $6,000,000 was advanced by National Headquarters to chapters facing exhaustion of their funds, and $300,000 was placed in state pools by chapters in areas of unusually high incidence. Expenditure includes a carry-over of care and treatment from previous epidemics. The carry-over from 1948, when more than 27,000 persons were stricken, probably will be the heaviest in the history of the foundation.

**Certification of Radiation Physicists.**—Beginning January 1, the American Board of Radiology will examine and certify physicists as radiation physicists. Three types of certificates will be granted: (1) radiological physics, (2) x-ray and radium physics and (3) medical nuclear physics. The second and the third are both included in the first. Each applicant for any one of the certificates in radiation physics will be required to meet several standards of education and experience. Certification will be based on examination to be conducted at the time and place of regular meetings of the American Board of Radiology. Information may be obtained from Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

**College of Surgeons Sectional Meetings.**—The third of a series of seven sectional meetings of the American College of Surgeons will be held in Kansas City on February 11 and 12, with headquarters at the Hotel President. While Illinois, Iowa, Nebraska, Kansas, Oklahoma, Arkansas and Missouri will be the main participating states there is no geographic restriction on attendance. Other sectional meetings will be held in Washington, D. C., Statler Hotel, March 15 and 16; Buffalo, Statler Hotel, March 21 and 22; Butte, Hotel Finlen, April 5 and 6, and Edmonton, MacDonald Hotel, April 12 and 13. The medical profession at large, medical students and hospital personnel are invited to join with the fellows of the college in the meetings. Conferences for hospital personnel will be held concurrently with the medical sessions.

**Grants for Research in Endocrinology.**—Requests to the Committee on Research in Endocrinology, National Research Council for grants-in-aid during the fiscal period from July 1 to June 30, 1950, will be received until February 28. Application blanks may be obtained by addressing the secretary, Division of Medical Sciences, National Research Council, 2101 Constitution Avenue, Washington 25, D. C. In addition to a statement of the problem and research plan, the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. The committee makes grants-in-aid of research in the general field of experimental and clinical endocrinology. However, applications for support of research in the problems of sex in the narrower sense cannot be given favorable consideration, and investigators seeking support in this field should direct their proposals to the Committee for Research in Problems of Sex of the National Research Council.

**Society Elections.**—At the recent meeting of the United States Chapter of the International College of Surgeons, Dr. Custis L. Hall, Washington, D. C., was installed as president; Dr. Henry W. Meyerding, Rochester, Minn., was chosen president-elect; Dr. Arnold S. Jackson, Madison, Wis., secretary, and Dr. Oscar B. Nugent, Chicago, treasurer. The college headquarters is at 1516 Lake Shore Drive, Chicago. ——The American Board of Anesthesiology at its annual meeting in October chose Drs. Paul M. Wood, New York, as president, and Curtiss B. Hickcox, Philadelphia, secretary.——The National Malaria Society meeting in New Orleans, December 5-9, installed Wendell D. Gingrich, Sc. D., Galveston, Texas, as president and chose Dr. Paul F. Russell, New York, president-elect. Martin D. Young, Sc. D., Columbia, S. C., continues as secretary-treasurer.——The Southern Surgical Society at its annual meeting in December chose Dr. Alfred Blalock, Baltimore, as president and Dr. John C. Burch, Nashville, Tenn., secretary.

**Central Surgical Association.**—The Central Surgical Association will meet in Cleveland, February 18-19, with headquarters at the Hotel Cleveland. A clinic day will be held February 17 at the Cleveland Clinic and Western Reserve University Medical School. Physicians presenting papers by invitation are: Frederick de Peyster, Chicago; Milton E. Klinger, Detroit; Oliver H. Beahrs, Rochester, Minn.; William Metcalf, Chicago; Daniel C. Thomson, Ralph D. Mahon, Jr. and Robert Berry, all of Ann Arbor, Mich.; Benjamin M. Gasul, Chicago; Raphael W., Albi, Chicago; Robert Lich, Jr., Joseph E. Maurer and Stephen B. Burdon, all of Louisville, Ky.; Winfield L. Butsch, Buffalo; Sidney Smith, Chicago; E. Thurston Thieme, Ann Arbor, Mich.; Edward J. Hill, Jr., and Harry C. Saltzstein of Detroit and John M. Hammer, Kalamazoo; John W. Derr, Detroit; Wayne B. Martin, Harold L. Method, Stanley W. Tuell and Harry Harding, all of Chicago; H. Harper Kerr, Omaha; Byron D. Bowen and Paul A. Fernbach, Buffalo; Richard H. Lillie, Robert W. Buxton and Ivan F. Duff, all of Ann Arbor, Mich.; D. Emerick Szilagyi and Joseph F. Alsop of Detroit; Wilfred G. Bigelow, Raymond O. Heimbecker and Robert C. Harrison, Toronto, Canada; Alexander J. Anlyan, Columbus, Ohio; Ivan B. Taylor and George R. Granger, Detroit; Max S. Sadove, Willis G. Diffenbaugh and Frances E. Sarver, Chicago; Robert H. LaBree, Duluth, Minn.; James Barron, Detroit, and Ward H. Eastman, Chicago. A symposium on hepatitis will be held Saturday at 12:15 p. m. with Drs. Thomas H. Seldon and James F. Weir, Rochester, Minn., and Isadore S. Ravdin, Philadelphia, taking part. At the annual dinner Friday at 7:30 p. m. Dr. Henry K. Ransom, Ann Arbor, Mich., will deliver the Presidential Address and Dr. Warren H. Cole, Chicago, will speak on "Nationalization of Medicine."

**Anniversary of Blood Program of Red Cross.**—The Red Cross announces that although the first regional center was established in Rochester less than a year ago, the Red Cross national blood program is now operating in every geographic area of the United States. Under the plan to provide the nation with blood and its derivatives for medical use, 19 programs including the statewide service in Massachusetts were in operation by December 20; more than 97,000 pints of blood had been collected and made available without charge to physicians at 614 hospitals and 32 clinics. Other centers have been established in Wichita, Kan.; Stockton, Los Angeles, and San Jose, Calif.; Atlanta, Ga.; Washington, D. C.; Tucson, Ariz.; Omaha, Neb.; Springfield and St. Louis, Mo.; Charlotte, N. C.; Detroit and Lansing, Mich.; Yakima, Wash.; Great Falls, Mont.; Columbus, Ohio, and St. Paul, Minn. Scheduled for early opening are regional centers at Portland, Ore.; Philadelphia; Nashville, Tenn.; Boise, Idaho, and Louisville, Ky. Each regional program maintains a center where the blood collected is tested, type, marked and stored under refrigeration for subsequent distribution. Mobile units serve blood collection centers in suburban and rural areas, in industrial plants, colleges and other places where groups of donors may be assembled. A part of the program is the distribution through state health departments of blood plasma and other derivatives processed from war surplus plasma returned to the Red Cross by the armed forces. Among the derivatives are immune serum globulin fibrinogen and serum albumin. During the last fiscal year, blood products made available through the Red Cross had an estimated current value of $17,000,000.

## PHILIPPINE ISLANDS

**Medical Mission to the Philippines.**—The World Health Organization and the Unitarian Service Committee sent a medical mission to the Philippines in late October made up of Drs. Howard C. Naffziger, San Francisco, chairman; J. Murray Steele, New York; Gumersindo Sayago, Cordoba, Argentina; Amador Guevara, San Jose, Costa Rica, and George Curtis, Columbus, Ohio. The group visited hospitals, clinics, puericulture centers and laboratories, held conferences and delivered lectures on venereal disease and its control in hospitals, clinics, universities and medical societies. On completion of the mission it made the following recommendations for venereal disease control work on the islands: (1) to broaden and extend the present work; (2) to intensify educational work throughout the islands and amplify the study of venereology in all medical schools; (3) to found a Philippine Society of Venereology to arouse professional interest; (4) to establish a statistical office to collect and study reports; (5) to establish technical and administrative autonomy in control work in the department of health; (6) to make available to physicians and nurses and social workers pamphlets on the diagnosis, treatment and control of venereal diseases; (7) to establish a coordinating social service to cover the islands; (8) to enact antivenereal legislation, and (9) to set up a serologic laboratory in each province.

## CORRECTION

**Fee for Course in Public Health.**—In the Dec. 25, 1948 issue of The Journal, page 1274, the following was published among the Postgraduate Courses for practicing physicians: University of North Carolina, School of Public Health, Chapel Hill, N. C.; Subject: Public Health; 9 months, September-June 1949; Fee—$100.00 per month. This should have been $100.00 per quarter.

# Marriages

Anthony J. Parisi, West Springfield, Mass., to Miss Shirley Louise Denny of Lebanon, N. H., November 6.

Robert Gaylord Brown, Circleville, Ohio, to Miss Nancy James Cowles at Greeneville, November 25.

Arthur J. Clarkin Jr., Norwood, R. I., to Miss Barbara Ann Hiborik of Johnstown, Pa., recently.

John Wesley Todd III, Staunton, Va., to Miss Patricia Ellen Coffey of Richmond, November 24.

James Francis Cooney, Milford, Mass., to Miss Rosemary Kuhn of Decorah, Iowa, November 27.

James Nicholas Dudley to Miss Virginia Baird Decker, both of Roanoke, Va., November 20.

Herman S. Shapiro, New York, to Miss Natalie Gelbard of Brooklyn, November 27.

# Deaths

**Samuel Torrey Orton** ⊕ New York; born in Columbus, Ohio, Oct. 15, 1879; University of Pennsylvania Department of Medicine, Philadelphia, 1905; specialist certified by the American Board of Psychiatry and Neurology, Inc.; formerly on the faculty of Harvard Medical School, Boston, and Columbia University College of Physicians and Surgeons; at one time head of the department of psychiatry at the State University of Iowa College of Medicine, Iowa City; lecturer in neurology at Clark University, Worcester, Mass., from 1913 to 1915; past president of the Association for Research in Nervous and Mental Disease and American Psychiatric Association; member of the American Neurological Association, American Association for the Advancement of Science and New York Academy of Medicine; served as clinical director and pathologist at the Worcester (Mass.) State Hospital and director of the State Psychopathic Hospital in Iowa City; neuropathologist at the New York Neurological Institute from 1929 to 1936; in 1943 consultant in language disabilities to the Institute of Pennsylvania Hospital, Philadelphia; scientific director of Pennsylvania Hospital, Philadelphia from 1914 to 1919; recipient of the Thomas W. Salmon Memorial Award and delivered the second lecture in 1936; for many years member of the editorial board of *Archives of Neurology and Psychology;* in 1945 received the honorary degree of doctor of science from the University of Pennsylvania School of Medicine; author of "Reading, Writing and Speech Problems in Children"; died in St. Francis Hospital, Poughkeepsie, N. Y., November 17, aged 69, of bronchopneumonia and fracture of hip.

**Robert Gaylord Davis** ⊕ Rear Admiral, M. C., U. S. Navy, retired, Santa Barbara, Calif.; born in Indianola, Iowa, May 29, 1883; Rush Medical College, Chicago, 1909; entered the U. S. Navy as a lieutenant (jg) in 1912 and advanced through the various ranks to captain in 1937; during his naval service served at the Hospital Corps Training School, Great Lakes, Ill., on the U. S. S. *Wright,* the U. S. S. *Langley,* the U. S. S. *Aroostook* and the U. S. S. *Saratoga;* during World War II served as district medical officer of the 16th Naval District and as medical officer in command of the Naval Hospital and Naval Medical Supply depot at Canacao, P. I., where he was captured by the Japanese forces Jan. 2, 1942 along with members of his hospital staff; liberated from a Japanese prison camp on Aug. 30, 1945 in Mukden, Manchuria, after having been interned for forty-three months; returning to the homeland in September 1945 was assigned to duty as a member of the Naval Retiring Board, San Diego, Calif., and placed on the retired list Oct. 1, 1946; among the decorations that he held was the Legion of Merit; advanced to the rank of rear admiral on the retired list in 1948; fellow of the American College of Physicians; died in San Diego, November 8, aged 65, of pulmonary embolism following an operation for carcinoma of the lung.

**John James Moren** ⊕ Louisville, Ky.; born in London, Ky., Aug. 31, 1871; Louisville (Ky.) Medical College, 1894; Hospital College of Medicine, Louisville, 1895; professor emeritus of neurology at the University of Louisville School of Medicine; member of the House of Delegates of the American Medical Association in 1917; fellow of the American College of Physicians; member of the Association for Research in Nervous and Mental Diseases; past president of the Kentucky State Medical Association and of the Jefferson County Medical Society; served during World War I; member of the examining board for inductees during World War II; member of the staffs of St. Joseph and Norton Memorial infirmaries, General and Children's hospitals and the Masonic Home; died in the Nichols Hospital October 26, aged 77, of hepatic insufficiency.

**John Dooley Lyttle,** Los Angeles; born in New York in 1889; Cornell University Medical College, New York, 1916; professor of pediatrics at the University of Southern California School of Medicine; formerly on the faculty of Columbia University College of Physicians and Surgeons; specialist certified by the American Board of Pediatrics; member of the American Pediatric Society, Harvey Society, New York Academy of Medicine and the American Association for the Advancement of Science; formerly associate attending pediatrician at the Babies Hospital and Vanderbilt Clinic and attending physician at the Willard Parker Hospital of New York; served during World War I; member of the American Red Cross Balkan Commission in Albania in 1919; director of pediatrics at the Children's Hospital; died in the Hospital of the Good Samaritan, November 26, aged 58.

**George Robert Osborn** ⊕ Tulsa, Okla.; born in Perry, Iowa, Feb. 17, 1875; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; fellow of the American College of Surgeons; past president of the Oklahoma State Medical Association and the Tulsa County Medical Society; one of the founders of the Tulsa Public Health Association; formerly a member of the council of the Southern Medical Association; served overseas during World War I; chief of the medical staff of the Salvation Army Home; affiliated with Hillcrest Memorial and St. John's hospitals; died October 10, aged 73.

**William Grady Mitchell** ⊕ San Angelo, Texas; University of Tennessee College of Medicine, Memphis, 1921; fellow of the American College of Physicians; member of the American Heart Association, Southern Medical Association and Texas Heart Association; served during World Wars I and II; formerly instructor in medicine at the University of Pennsylvania School of Medicine, Philadelphia; on the staff of the Shannon Hospital, where he was a member of the board of directors; director of the clinical laboratory at St. John's Hospital; died in Seattle October 8, aged 52.

**Harry Aldrich** ⊕ Fort Wayne, Ind.; Indiana University School of Medicine, Indianapolis, 1914; past president of the Grant County Medical Society; formerly county coroner; served during World War I; affiliated with the Methodist Hospital and the Lutheran Hospital, where he died October 31, aged 63, of periarteritis nodosa.

**Arthur Reginald Butler,** Newington, Va.; Columbian University Medical Department, Washington, D. C., 1899; died November 14, aged 76.

**William P. Dupler,** Crooksville, Ohio; (licensed in Ohio in 1896); formerly county coroner; died October 30, aged 87, of senility.

**Harold Winston Eckel,** Cincinnati; University of Cincinnati College of Medicine, 1938; served during World War II; member of the American Medical Association; affiliated with Christ Hospital, where he died November 5, aged 35, of carcinoma of the transverse colon.

**Jerome Charles Evanson** ⊕ Assistant Surgeon, Lieutenant (jg) U. S. Navy, Echo, Minn.; Marquette University School of Medicine, Milwaukee, 1946; entered the regular navy in 1947; last duty station, Yard Dispensary, Puget Sound Naval Shipyard, Bremerton, Wash.; died in the U. S. Naval Hospital, Bremerton, November 19, aged 26, of blastomycotic abscess of the cerebellum.

**Lonie Clarence Floyd** ⊕ Olanta, S. C.; Medical College of the State of South Carolina, Charleston, 1910; member of the Selective Service Board during World War II; died November 2, aged 66, of coronary occlusion.

**William Schaffer Glenn Jr.,** State College, Pa.; Eclectic Medical College, Cincinnati, 1915; served overseas during World War I; died November 9, aged 60, of heart disease.

**Brooks David Good** ⊕ Colorado Springs, Colo.; Tulane University of Louisiana School of Medicine, New Orleans, 1919; member of the American College of Chest Physicians; served during World War I; physician in charge of the Cragnor Sanatorium; died in St. Francis Hospital, November 4, aged 52, of acute hepatitis and acute nephritis.

**Walter James Halloran** ⊕ Yonkers, N. Y.; Fordham University School of Medicine, New York, 1918; fellow of the American College of Surgeons; member of the National Gastroenterological Association; served during World War I; physician to the selective service board during World War II; for many years medical examiner to the Yonkers Civil Service Commission; affiliated with St. John's Riverside Hospital; died November 14, aged 52, of coronary occlusion.

**Charles Russell Hancock,** Atlanta, Ga.; Medical College of Ohio, Cincinnati, 1904; member of the American Medical Association; died in St. Joseph's Infirmary in November, aged 69, of carcinoma of the prostate.

**Orrin Winfield Haulman** ⊕ Youngstown, Ohio; Western Reserve University School of Medicine, Cleveland, 1918; affiliated with the South Side Unit and North Side Unit of the Youngstown Hospital, where he died November 3, aged 60, of coronary thrombosis.

**Laurence Sherman Jennings,** San Francisco; University of Chicago School of Medicine, 1939; member of the American Medical Association; on the staff of the Stanford University Hospital; served during World War II; died November 5, aged 34.

**Manfred Kraemer** ⊕ Newark, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1929; fellow of the

American College of Physicians; member of the National Gastroenterological Association; past president of the New Jersey Gastroenterological Society; specialist certified by the American Board of Internal Medicine; served during World War II; consultant at the Irvington (N. J.) General Hospital; affiliated with Presbyterian, St. James and Newark City hospitals; died November 12, aged 44, of coronary occlusion.

**Leo Thomas McKee** ⊕ St. Marys, Pa.; Georgetown University School of Medicine, Washington, D. C., 1928; affiliated with the Elk County General Hospital, Ridgway, and the Andrew Kaul Memorial Hospital; died in the Robert Packer Hospital, Sayre, October 26, aged 45, of carcinoma of the liver.

**Samuel Emerson McMaster** ⊕ Akron, Ohio; Ohio Medical University, Columbus, 1906; affiliated with Peoples Hospital, where he died October 31, aged 67, of coronary thrombosis.

**Howard Douglas Mailey,** Oakland, Calif.; Boston University School of Medicine, 1942; certified by the National Board of Medical Examiners; specialist certified by the American Board of Radiology, Inc.; member of the American Medical Association, Massachusetts Medical Society and the New England Roentgen Ray Society; at one time affiliated with the Lahey Clinic in Boston; died in Providence Hospital October 14, aged 33, of acute coronary occlusion, arteriosclerosis and diabetes mellitus.

**Seth Heustis Martin,** Morrisville, Vt.; Baltimore Medical College, 1910; member of the American Medical Association and of the American Urological Association; served during World War I; on the staff of the Copley Hospital; formerly on the faculty of the University of Vermont College of Medicine and on the staff of the Mary Fletcher Hospital, in Burlington, where he died October 27, aged 66, of hypertension and arteriosclerosis.

**William Edgar Matthews,** Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1887; member of the American Medical Association; past president of the Cambria County Medical Society; formerly chief medical inspector for the state board of health and medical director of Cambria County; during World War I chief examining physician to the draft board; affiliated with the Conemaugh Valley Memorial Hospital, where he died October 29, aged 88, of arteriosclerosis and chronic nephritis.

**Charles W. Miller,** Preston, Iowa; State University of Iowa College of Medicine, Iowa City, 1887; served as county coroner and as city health physician; died in the City Hospital, Savanna, Ill., October 11, aged 89, of leukemia.

**Lawrence T. Minish** ⊕ Frankfort, Ky.; Kentucky School of Medicine, Louisville, 1898; an officer during World War I; served as vice president of the Kentucky State Medical Association and as a member of the state board of health; on the staff of King's Daughters' Hospital; died October 20, aged 71, of cerebral hemorrhage.

**Hewitt Clyde Myers** ⊕ Steelton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; past president of the Harrisburg Academy of Medicine and the Dauphin County Medical Society; for many years surgeon for the Pennsylvania Railroad; died October 24, aged 73, of acute cardiac dilatation.

**Samuel Heyman Nerenstone,** New York; Cornell University Medical College, New York, 1923; member of the American Medical Association; on the staff of the Lincoln Hospital; died October 25, aged 50.

**Hubert Earl Northrup,** Detroit; Detroit College of Medicine, 1912; past president of the Detroit Obstetrical and Gynecological Society; served during World War I; on the staff of the Highland Park (Mich.) General Hospital; died in Highland Park, Mich., October 31, aged 61.

**Oscar Joel Nothenberg** ⊕ Chicago; Dearborn Medical College, Chicago, 1907; specialist certified by the American Board of Otolaryngology; affiliated with the Swedish Covenant and American hospitals; died November 9, aged 74, of coronary thrombosis.

**Jeptha Marion Olin,** Vermilion, Ohio; Cleveland Homeopathic Medical College, 1899; died September 30, aged 85, of myocardial infarction.

**James Patrick Owens,** Memphis, Tenn.; College of Physicians and Surgeons, Memphis, 1910; member of the American Medical Association; served overseas during World War I; affiliated with St. Joseph's Hospital; died October 5, aged 61, of coronary occlusion.

**Charles Russell Parsons,** Sweet Springs, Mo.; University of Tennessee College of Medicine, Memphis, 1938; member of the American Medical Association; interned at Kansas City (Mo.) General Hospital; on the visiting staffs at Research Hospital in Kansas City and Fitzgibbon Memorial Hospital in Marshall; died in Morrisville, October 22, aged 41, of injuries received in an automobile accident.

**Edgar Allen Patton,** Knoxville, Tenn.; Mississippi Medical College, Meridian, 1911; Memphis (Tenn.) Hospital Medical College, 1913; served during World War I; for many years affiliated with the Veterans Administration; died October 11, aged 62, of congestive heart failure.

**Lewis Luallen Patton,** Chattanooga, Tenn.; Meharry Medical College, Nashville, 1912; died recently, aged 64, of cerebral hemorrhage.

**Howard Love Prince** ⊕ Rochester, N. Y.; Cornell University Medical College, New York, 1907; served during World War I; member of the American Association of Industrial Physicians and Surgeons; affiliated with Rochester General Hospital, Strong Memorial Hospital, Genesee Hospital and the County Infirmary; died November 18, aged 63.

**Edward North Reed** ⊕ Santa Monica, Calif.; Rush Medical College, Chicago, 1904; an Associate Fellow of the American Medical Association; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served during World War I; affiliated with the Orthopaedic Hospital in Los Angeles and the Santa Monica Hospital; died in the Veterans Administration Hospital, West Los Angeles, October 18, aged 71.

**Gardner Shaw Reynolds,** Danville, Ill.; University of Minnesota Medical School, Minneapolis, 1924; specialist certified by the American Board of Radiology; certified by the National Board of Medical Examiners; member of the American Medical Association, Radiological Society of North America and the American College of Radiology; served as radiologist at St. Elizabeth Hospital; died in the Veterans Administration Hospital, St. Cloud, Minn., October 16, aged 50, of coronary thrombosis.

**Henry Gilbert Reynolds** ⊕ Paducah, Ky.; Louisville (Ky.) Medical College, 1897; specialist certified by the American Board of Otolaryngology; past president of the Kentucky State Medical Association and the McCracken County Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staff of Illinois Central Hospital; died October 18, aged 76, of cerebral hemorrhage.

**Addison O. Roberts,** Round Lake, N. Y.; Albany (N. Y.) Medical College, 1882; served as school physician and as health officer both of Rensselaer and in the town of Malta; on the visiting staff of Memorial Hospital in Albany; died September 28, aged 92, of arteriosclerosis.

**Thomas Avery Rogers** ⊕ Plattsburg, N. Y.; Albany (N. Y.) Medical College, 1896; died recently, aged 75, of hypertensive cardiorenal disease and cerebral vascular accident.

**James Wilson Rollo** ⊕ Lubbock, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1913; served during World War I; local surgeon for the Atchinson, Topeka and Santa Fe Railroad; for many years health officer; died recently, aged 65, of heart disease.

**Abraham Rose,** Elizabeth, N. J.; Medico-Chirurgical College of Philadelphia, 1914; member of the American Medical Association; physician to the police department; on the staffs of the Alexian Brothers Hospital and St. Elizabeth's Hospital, where he died October 31, aged 61, of coronary thrombosis and diabetes mellitus.

**Robert M. Ross,** Temple City, Calif.; Beaumont Hospital Medical College, St. Louis, 1898; died in St. Luke's Hospital, Pasadena, October 16, aged 75, of cerebral hemorrhage and hypertension.

**Isaac Machol Rubin** ⊕ Cleveland; University of Wooster Medical Department, Cleveland, 1906; on the courtesy staff of the Mount Sinai Hospital, where he died October 22, aged 68, of carcinomatosis.

**Louis Frederick Ruschhaupt** ⊕ Milwaukee; Rush Medical College, Chicago, 1902; associate clinical professor of medicine at Marquette University School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; affiliated with Milwaukee County Hospital, Johnston Emergency Hospital and the Evangelical Deaconess Hospital, where he died October 1, aged 69, of carcinoma of the bladder.

**Oscar John Ruzicka,** Brooklyn; Eclectic Medical College of the City of New York, 1908; also a pharmacist; died November 6, aged 72.

**William Spiller Sayers,** Wytheville, Va.; University of Virginia Department of Medicine, Charlottesville, 1893; formerly health officer of Norfolk; died October 31, aged 76, of acute cardiac failure.

**Jacob Foster Shelley** ⊕ Elmdale, Kan.; Rush Medical College, Chicago, 1891; died in the Newman Memorial County Hospital in Emporia, October 23, aged 83, of senility.

**Benjamin Harry Sherman** ⊕ Los Angeles; Northwestern University Medical School, Chicago, 1904; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc.; on the staff of Los Angeles County Hospital; died in Hollywood Presbyterian Hospital October 18, aged 69, of aplastic anemia.

**Hiram Edward Silverstone,** Kansas City, Mo.; Missouri Medical College, St. Louis, 1898; died in Kansas City, Kan., October 19, aged 72, of ventricular fibrillation.

**Alexander Hamilton Stevens Jr.,** New Bern, N. C.; University of Georgia Medical Department, Augusta, 1932; member of the American Medical Association; served during World War II; killed October 21, aged 43, in an automobile accident.

**Alexander Porter Stewart,** St. Petersburg, Fla.; University of Toronto Faculty of Medicine, Toronto, Canada, 1905; past president of the Lyon County (Ia.) Medical Society; served during World War I; died in Veterans Administration Hospital, Bay Pines October 10, aged 68, of coronary thrombosis.

**Wallace T. Stewart,** Cynthiana, Ky.; University of Louisville Medical Department, 1890; died September 14, aged 80, of cerebral hemorrhage.

**Samuel Henry Stith,** Brandenburg, Ky.; University of Nashville (Tenn.) Medical Department, 1901; served during World War I; major, medical reserve corps, not on active duty; medical examiner for the county draft board during World War II; died in Louisville October 19, aged 79, of carcinoma of the pancreas.

**Frank Ulmer Swing** ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1904; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; affiliated with St. Mary's and St. Francis hospitals; died recently, aged 75, of cerebral hemorrhage.

**Samuel Aaron Tannenbaum,** New York; Columbia University College of Physicians and Surgeons, New York, 1898; died October 31, aged 74, of cerebral hemorrhage.

**Daniel E. Taylor,** Velpen, Ind.; Hospital College of Medicine, Louisville, Ky., 1903; member of the American Medical Association; affiliated with Welborn Memorial Baptist Hospital, Evansville; died October 25, aged 79, of carcinoma of the stomach.

**Ernest Burdett Taylor,** Toledo, Ohio; Toledo Medical College, 1903; member of the American Medical Association and the Academy of Medicine of Toledo and Lucas County; served during World War I; on the visiting staffs of the Toledo and St. Vincent's hospitals; on the honorary staff of Flower Hospital, where he died October 6, aged 69, of cerebral thrombosis and gastrointestinal hemorrhage.

**Giovanni Tenca,** New York; Regia Università degli Studi di Parma, Facoltá di Medicina e Chirurgia, Italy, 1920; for many years medical examiner for the Equitable Life Assurance Society; died in the Memorial Hospital October 16, aged 53, of lymphosarcoma.

**James Grimes Thames,** Milton, Fla.; Atlanta College of Physicians and Surgeons, 1910; died October 2, aged 64, of heart disease.

**David L. Tilderquist** ⊕ Duluth, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; affiliated with St. Luke's Hospital and St. Mary's Hospital; died September 26, aged 76, of cerebral thrombosis.

**Johnson Edward Turnage,** Kosciusko, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; member of the American Medical Association; on the staff of the Montfort Jones Memorial Hospital, where he died October 26, aged 68, of coronary thrombosis.

**Arthur Dale Tuttle,** Live Oak, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1935; member of the American Medical Association; certified by the National Board of Medical Examiners; served during World War II; died October 9, aged 44.

**Carl Henry Wachenfeld,** St. Louis; Washington University School of Medicine, St. Louis, 1910; member of the American Medical Association; served during World War I; member of the staff of the Missouri Baptist Hospital; medical director of the State National Life Insurance Company; died in the Veterans Administration Hospital, Jefferson Barracks, October 18, aged 60, of heart disease.

**William Greenleaf Ward,** Lynn, Mass.; Harvard Medical School, Boston, 1899; formerly library trustee of the school board; on the courtesy staff of the Lynn Hospital, where he died October 28, aged 75, of arteriosclerosis.

**Henry Washeim Jr.** ⊕ Utica, N. Y.; Yale University School of Medicine, New Haven, 1928; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; affiliated with St. Luke's, St. Elizabeth and Utica State hospitals; died October 20, aged 48, of cerebral hemorrhage and cerebral aneurysm.

**Lionel Bernard Watkins,** Nashville, Tenn.; University of Nashville Medical Department, 1901; died October 22, aged 71, of cirrhosis of the liver, chronic nephritis and hypertension.

**Edward Andrew Weisser** ⊕ Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1898; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staffs of the Roselia Foundling and Maternity Hospital and St. Francis Hospital, where he died October 18, aged 72, of metastatic carcinoma.

**Leonard Lee Welch,** Marietta, Ga.; University of Pennsylvania School of Medicine, Philadelphia, 1921; member of the American Medical Association; member of the board of directors of the Marietta Hospital; surgeon for the Nashville, Chattanooga and St. Louis Railway; died in Atlanta October 19, aged 53, of coronary occlusion.

**Hippolyte Marcus Wertheim,** New York; born in New York, Feb. 12, 1898; University and Bellevue Hospital Medical College, New York, 1920; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; associate professor of clinical surgery at the New York University College of Medicine and past president of the alumni association; affiliated with Bellevue, French and Goldwater Memorial hospitals; died November 8, aged 50, of carcinoma of the pancreas.

**George Lewis Wickes** ⊕ Medical Inspector, Commander, U. S. Navy, retired, Ventnor, N. J.; New York University Medical College, New York, 1896; entered the U. S. Navy on April 27, 1904 and retired June 30, 1936; died in the U. S. Naval Hospital, St. Albans, N. Y., September 30, aged 74, of carcinoma of the bladder.

**Morrill Edwin Withrow,** International Falls, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1897; served as mayor and as city and county health officer; formerly affiliated with the U. S. Public Health Service; died October 13, aged 78, of cardiac decompensation and cerebral hemorrhage.

**James McClain Young,** Albany, Ill.; Chicago College of Medicine and Surgery, 1913; formerly owner of a hospital bearing his name; affiliated with Kewanee Public and St. Francis hospitals in Kewanee; died October 17, aged 62, of cerebral hemorrhage.

---

## DIED WHILE IN MILITARY SERVICE

**William Francis Conway** ⊕ Lieutenant Colonel, M.C., U. S. Army, Carlisle, Pa.; George Washington University School of Medicine, Washington, D. C., 1932; appointed first lieutenant, medical corps, regular army, Dec. 7, 1936; promoted through the various grades to that of lieutenant colonel on March 5, 1943; died Aug. 8, 1943, aged 36, of carcinoma.

**Sarkis Der Sarkissian,** Chicago; University of Michigan Medical School, Ann Arbor, 1926; member of the American Medical Association; served overseas during World War II; a flight surgeon and assistant post surgeon with the rank of lieutenant colonel, medical reserve corps of the U. S. Army attached to the Sheppard Field Air Base at Wichita Falls, Texas; died near Muldrow, Okla., November 1, aged 48, of injuries received in an airplane crash.

*(From Our Regular Correspondent)*

Dec. 18, 1948.

### Unsatisfactory Remuneration of Doctors in the National Health Service

Further experience with the National Health Service produces increased dissatisfaction of the doctors and something different from the rosy picture which the Minister of Health said would be the admiration of the world. Complaints of increased work and falling incomes become louder, especially from practitioners in rural, semirural and suburban areas where the proportion of the elderly and the invalid is high. At the annual conference of local medical committees held in the British Medical Association House it was agreed that the amount of work imposed on the doctor by the inclusion of the whole population, instead of the workers only, has been greatly increased and that, while in certain parts of the country the doctor's financial position may have been improved, there are large areas where his income has been halved or even further reduced.

Dr. H. Guy Dain, Chairman of the Council of the British Medical Association, agreed that the present capitation fee is grossly inadequate. He illustrated the evils of the "something for nothing" pointed out in previous letters to THE JOURNAL. It is not difficult, he said, to foresee the extra work which will fall on the doctor. It will be a strange mother nowadays, when the doctor is in attendance, who does not ask him to look at other members of the family. It is now not a question of visiting a patient but of visiting a family. It is overwhelming us and in the forthcoming winter may cause a complete breakdown of the whole service. On the question of pay, not only is the capitation fee insufficient, but it is not properly distributed. A doctor who is suffering hardship should have an immediate claim to be paid out of special funds.

Dr. E. A. Gregg, chairman of the Insurance Acts Committee, said that in view of the complaints from all over the country they cannot wait for further details before putting forward a claim for improved remuneration, that in rural, semirural, suburban and certain special areas doctors have realized that their incomes are vanishing, that the doctor has lost his private practice but the population is not sufficient for a list which would maintain his economic position and that the mileage allowance for rural practitioners is insufficient.

A fundamental difficulty was voiced by one of the delegates. Today the income of doctors bears no relation to the amount of work done. A large list means a large income, but is an inducement to perfunctory work; indeed, may render any other impossible. But a more conscientious doctor, who will not undertake more patients than he can properly attend, gets a correspondingly small income.

### War Against the Tsetse Fly

The Government has published three progress reports on the war against the tsetse fly which is being waged in Africa. Though much is now known about this fly, which is the carrier of grave disease to man and cattle, it still has a grip on an area of Africa twice as large as the United States. Prof. P. A. Buxton, who is studying the problem in East Africa and the Rhodesias, has concluded that the types of fly which inhabit narrow strips beside water have been controllable for years, though often at undue cost. Those that now inhabit belts of bush can be expelled in certain environments, though by no means in all. The work of the last twenty years has been recolutionary, and its importance is not yet realized, even in Africa. He challenges the belief that the tsetse fly is everywhere on the advance, which he attributes to the fact that its arrival in new areas is immediately recognizable by its effects, whereas its retreats require careful research to discover. He gives figures to show that infection and death from the disease in man are so low as to be unimportant. It is the disease among cattle, on which so much of the African population depend, that above all needs to be tackled.

Prof. T. M. Davey deals with the conditions in West Africa and in non-British territories. In British West Africa the disease is a fundamental barrier to progress. It causes a direct loss, at a low estimate, of $4,000,000 a year. Indirect losses cannot be computed but are causing progressive impoverishment of the people.

Dr. T. A. Nash's report on the Anchau settlement scheme describes the clearance of a corridor 70 miles long and 10 miles wide in Northern Nigeria. Here under the Sleeping Sickness Service of the Nigerian Medical Department 60,000 persons have been settled in a new hygienic tsetse-free town.

### International Union Against Tuberculosis

A meeting of the executive committee and council of the International Union Against Tuberculosis was held at the Union's Headquarters, 66 Boulevard St-Michel, Paris, September 27-29, under the presidency of Professor Lops de Carvalho. The representatives of seventeen nations were present. The American representatives included: Dr. Perkins, managing director of the National Tuberculosis Association, Dr. Martin Cummings, Dr. Reuling, Dr. Kendall Emerson, Dr. Hilleboe and Mr. Hopkins.

During the administrative session Prof. Etienne Bernard, professor of phthisiology at the University of Paris, was elected secretary general of the Union, to replace the late Professor Besançon. Prof. Omodei Zorini, director of the Carlo Forlanini Institute, in Rome, was nominated to represent Italy on the executive committee. The first scientific meeting was devoted to "Recent Studies of Media for the Cultivation of the Tubercle Bacillus." The opening report was read by Dr. Cummings, director, Tuberculosis Evaluation Laboratory, U. S. Public Health Service, who gave an account of the progress achieved through the researches of René Dubos. Prof. Paul Courmont, Prof. Hauduroy, Prof. Gernez-Rieux, Drs. André Meyer and Costil, Dr. Bretey and Drs. Braun and Kreiss. Prof. Omodei Zorini took part in the discussion. Prof. Etienne Bernard read the opening report on "Treatment of Nonmiliary Tuberculosis in the Adult with Streptomycin." According to him in acute pneumonic or bronchopneumonic forms streptomycin enables the patient to endure a dangerous situation; in subacute and nodular forms the action of streptomycin is in most cases remarkable and similar to what has been observed with miliary forms. As regards cavernous tuberculosis, the closure of a cavity with the disappearance of bacilli has been secured in 10 per cent of cases. The combined treatment, streptomycin with collapse therapy or streptomycin with surgical treatment has proved most valuable and has great prospects. The report gave rise to a discussion in which the following speakers took part: Prof. V. Fici, Dr. Pierre Bourgeois, Dr. Jullien, Prof. Costantini, Prof. Omodei Zorini, Prof. U. Carpi and Dr. Duroux.

The next meeting of the Council will be held in Paris in July 1949.

### Sensitivity to Streptomycin in Nurses

In the tuberculosis ward of the Laennec Hospital, Professor E. Bernard, Melle Lotte and C. Wolff examined nurses who had been in contact with streptomycin. Out of 70 nurses, 33 have shown either oculopalpebral disorders or eczematous eruptions on the hands and wrists and in the periorbital and peribuccal regions; in 9 cases the eruptions extended to the thorax, legs and feet; in 7 cases there was pruritus only at the same sites. These disorders occurred in one to three months in 17 cases, three to six months in 16, and more than six months in 7. In most of the cases, these disorders improved or disappeared after a few days of suspension of work (save for 1 case, when eczematous patches still persisted after several months) and they reappeared almost immediately when contact with streptomycin was resumed. In 8 cases, discrete disorders were experienced and disappeared without necessity for interruption of work. The authors have made cutaneous tests with streptomycin on 40 nurses who had been in contact with streptomycin for a long time. Out of 28 nurses showing reactions, 20 have positive reactions and 8 negative; among 12 nurses showing no disorders, though they had handled the antibiotic for nine to twelve months, six tests gave positive reactions and 6 negative. Disorders may not occur in subjects with positive reactions, if the necessary precautions, wearing of gloves and spectacles, are taken.

### Doctor Honoris Causa

The degree of Doctor Honoris Causa has been conferred on the following: Sir Jack Drummond, F.R.S., professor of biochemistry at the London University, Corter professor of pediatric clinics of the Leyde Faculty of Medicine; Dos Santos, professor at the Lisbon Faculty of Medicine; John Maurice Clark, professor at Columbia University, New York; J. C. Chavez, director of the Institute of Cardiology of the Mexico Faculty of Medicine, and L. C. Pauling, professor of chemistry at the California Institute of Technology, Pasadena, Calif.

## DENMARK

*(From Our Regular Correspondent)*

Copenhagen, Dec. 8, 1948.

### Inauguration of the New Domus Medica

On the night of June 18, 1944, the Germans burst into the headquarters of the Danish Medical Association, the beloved Domus Medica, symbol of all that is best in the Danish medical profession, bombing it and burning it to the ground. By this senseless act of hooliganism, the Germans imagined that the ever growing activity of the Danish doctors in the underground movement against them would be paralyzed. Altogether, twenty-one Danish doctors were murdered by the Germans, either in cold blood after a semblance of a trial, by anonymous assassination or by the slow torture of the concentration camp. But the spirit of the Danish doctors was never broken, and they soon set about the task of raising a new Domus Medica after the evacuation of Denmark by the Germans. But the funds and time required for rebuilding the Domus Medica on the old site were such that the situation seemed almost hopeless. Then, suddenly and quite unexpectedly, the Danish Medical Association was able to purchase an already existing, palatial building, the old Plessen Palace. The cost was high, and the Association had to exhaust nearly all its funds, but it was a magnificent bargain all the same.

On Oct. 22, 1948, in the presence of the King and Queen of Denmark and distinguished representatives of the medical profession at home and abroad, the new Domus Medica was solemnly inaugurated, and a mural memorial to the twenty-one Danish doctors murdered by the Germans was unveiled. Speaking on this occasion, Professor Mogens Fog drew attention to this memorial, which is the first object to strike the eye as the visitor enters the new Domus Medica. The inscription between the two rows of names is taken from two lines of a poem composed by Dr. Aage Berntsen in honor of those glorious days in May 1945 when Denmark became once again a free country. These lines run: "Du hörte op med at vaere, men Danmark lever med aere," which may be translated with: "You ceased to live, but Denmark lives with honor." Thanks to the spaciousness of the new Domus Medica, it will be possible for part of it to be turned into a residential college for students whose parents are doctors. Other sections of the building will be put at the service of various scientific bodies other than the Danish Medical Association, whose expenses will thereby be reduced to a certain extent.

### Claim Lowest Tuberculosis Death Rate

The claim, implied by this heading, that Denmark has a lower tuberculosis death rate than any other country in the world may possibly provoke a challenge from some quarter or other, but it will be a close race in any case. In 1939, the Danish tuberculosis death rate had been reduced to 34 per hundred thousand. During the following, wartime years, there was a slight rise reflecting wartime conditions, but as early as 1943 this slight rise was checked, and in 1945 the figure was down to 33. In 1946 it was down still further to 32, and in 1947 it was down to the record low level of 30 per hundred thousand. In this year the tuberculosis death rate was nearly twice as high in Copenhagen, where it was 44, as it was in the country districts (23 per hundred thousand). Why did World War II have so slight an influence on the tuberculosis death rate, while World War I sent it rocketing aloft? Professor Knud Faber found an answer to this question at the last annual meeting of the Danish National Association Against Tuberculosis, pointing out that in World War I Denmark allowed herself to be drained of animal food stuffs, meat in particular. In World War II, and in spite of being occupied by the German army, Denmark was able to keep up a rather steady supply of meat, butter and other farm products for home consumption. The Germans were so afraid of killing the goose that lays golden eggs that the Danish farmer was encouraged to produce food diverted by the ingenuity of the Danes to home consumption.

A curious and at first sight disquieting observation made by Professor Faber is that there has lately been a decided rise in the number of new notifications of tuberculosis in Denmark. In the three years 1944, 1945 and 1946 the number of new notifications of tuberculosis was 3,300, 3,500 and 4,100, respectively. In his opinion this rise is much more apparent than real, for it reflects the growing attention paid to environmental studies in the course of which many new cases are unexpectedly discovered. It is a pleasing thought that Denmark has of late made antituberculosis work an article for export; witness the pioneer work of the Danish Red Cross with the organizations of teams of doctors for carrying out BCG vaccinations on wholesale lines in various European countries.

### "Antabus," A New Remedy for Alcoholism

In the organ of the Danish Medical Association (*Ugeskrift for Laeger*) for October 21, Dr. O. Martensen-Larsen has given an encouraging account of his experiences in some 300 cases of alcoholism with treatment with tetraethylthiuram disulfide, or "antabus," during the first part of 1948. Of the first 50 patients kept under observation for more than six months, 35 had recovered or achieved considerable improvement. The remaining 15 had discontinued this treatment for some reason or other. Little happens when "antabus" tablets are swallowed by themselves, but when they are followed up by even small doses of alcohol they give rise to such discomfort that the patient soon acquires a dislike for alcohol. It is suggested that this reaction depends on the formation of acetaldehyde in the blood, experiments on animals having shown that the intravenous injection of acetaldehyde can give rise to a similar reaction.

## ITALY

*(From Our Regular Correspondent)*

FLORENCE, Dec. 10, 1948.

### Medical-Surgical Association of Romagna

A meeting of this association was held in San Marino with Professors Fontana and Cavina as chairmen. Professor Pieri discussed vagotomy in the treatment of gastric disorders. He reported his research on the physiology of the vagus nerve in man and described its clinical application, i. e., by practicing vagotomy in the treatment of certain gastric disturbances. His experience is based on 144 patients operated on, 8 of them with gastric neurosis and 136 with ulcer. In the former group treatment was successful in 3 cases of hypersthenic dyspepsia, 2 cases of mediogastric spasm and 2 cases of intractable vomiting. Results were less favorable in 1 case of gastric attacks from tabes. The results obtained with vagotomy in the treatment of gastric ulcer were on the whole very satisfactory, and the speaker believes it safe to conclude that vagotomy can cure peptic ulcer in its various manifestations and is likely also to prevent it.

Professor Pieri illustrated with many pictures the technic of supradiaphragmatic and infradiaphragmatic vagotomy. Six of 144 patients operated on died (mortality rate of 4.15 per cent), 4 of them from bronchopneumonia and 2 from circulatory collapse. In the discussion which followed the report, some in attendance were in favor of Professor Pieri's statements; Franchini, however, expressed doubt whether such intervention may be harmful to the patient. According to Professor Schiassi, although the vagus nerve may be of etiologic importance in gastric ulcer, a concurrence of other anatomic and psychonervous conditions must be considered. The so-called ulcer disease affects a large number of patients whom Schiassi considers neurotic, in whom repeated psychic disturbances may induce the occurrence of ulcer. Constitutional causes and nervous and alimentary disorders slowly prepare the ground for the formation of gastric ulcer, and some symptoms, for example, an inflammation of the stomach observed at the operation table, may not be attributed to the action of the vagus.

Battistini likewise, who studied the research of American and Italian authors, recommended caution concerning the fate of patients who submit to the complete interruption of a nerve which dominates the entire abdominal vegetative life. He recalled that Walters and his co-workers at the Mayo Clinic obtained results with vagotomy which were not very favorable.

Cavina of Florence discussed Millin's new method of prostatectomy, described the technic and some of his own modifications of this method which may simplify the original Millin' operation. After preparatory treatment with penicillin, calcium and vitamin K, and after general anesthesia with ether, the patient is placed in the Trendelenburg position. A short median suprapubic incision in the abdominal wall is made, the rectus muscles are separated with a Gosset bistoury and the bladder and the prostatic capsule are exposed. The latter is then incised with a median incision, and one proceeds to enucleate the adenoma with the index or middle finger of the right hand while the index and middle finger of the left hand are introduced in the rectum as in Freyer's operation. The adenoma may be removed with a suitable forceps. From the meatus of the urethra across the prostatic cavity one introduces into the bladder a large Nélaton catheter. The breach of the prostatic capsule is sutured as well as the abdominal wall after previous dusting of the Retzius' cavity with sulfonamide powder. The advantages of this new method are minimum shock, little hemorrhage and little postoperative suffering. In the hospital of S. Giovanni di Dio in Florence, which is under the direction of the speaker, 30 patients have been operated on according to this method and the results were highly satisfactory.

### Roentgen Therapeutic Experience in Syndromes of Disturbed Metabolism

At a meeting of the Medical Academy of Genoa, Cignoli stated that the effects of roentgen therapy on the various tissues which constitute the epiphyses of bones cannot at present be attributed to a simple and single mechanism consisting of proteinemic equilibrium. The speaker restated that it may be useful to study further the Hand-Schüller-Christian syndrome, a many-faceted disorder with functional disturbances and anatomopathologic changes which involve the reticuloendothelial system, the water metabolism, the lipid metabolism; diabetes insipidus, another syndrome with many forms, with predominance of water-salt metabolism and of protein metabolism; lipid nephrosis, with sodium, water, lipid and protein changes. The speaker concluded his report by stating that a satisfactory interpretation of the effects of roentgen therapy on the bones will be possible only when experience is available on a large number of cases similar to the syndromes mentioned, together with a large number of additional observations on patients such as those mentioned.

## PERSIA

*(From a Special Correspondent)*

BAHREIN ISLAND, PERSIAN GULF, Dec. 13, 1948.

### Medical Congress in Persian Gulf Area

A Medical Congress was held under the auspices of the Bahrein Island Medical Society on Nov. 4, 1948. All doctors working in the Persian Gulf area were invited, and thirty-six doctors were able to attend. This congress, the first of its kind in this area, was in some ways of an experimental nature. It was desired primarily to exchange ideas held by European, American and Indian doctors as to etiology, diagnosis and treatment of diseases endemic in this area. Secondly, it was felt desirable to determine interest and the number of doctors who could attend such a congress with a view to forming a more closely knit organization of medical men. Thirdly, it was believed that a meeting of this kind would do much so stimulate medical thinking in a section of the world where there is little access to large medical centers.

After a few introductory remarks by the chairman, Dr. Robert J. Biggar, Chief Surgeon to the Bahrein Petroleum Company Limited and president of The Bahrein Island Medical Society, the following articles were read:

Report and Personal Interpretation of the International Industrial Congress at London, last September, Dr. A. J. S. Perfect, the Bahrein Petroleum Co. Ltd.

Tuberculosis of the Peritoneum Treated with Streptomycin: Report of Cases, Mr. Allen-Mersh, Kuwait Oil Co., Kuwait.

The Diarrheas Encountered in This Area, Dr. H. H. Golz, Arabian American Oil Co., Dhahran, Saudi Arabia.

External Otitis, Its Etiology and Management, Dr. A. Anderson, Anglo Iranian Oil Co., Abadan, Iran.

Back Pain—Causes and Diagnosis, Dr. Joseph De Lougherty, Arabian American Oil Co., Dhahran, Saudi Arabia.

The Soft Penile Ulcer, Major Wm. C. Marrett Jr., M. C., U. S. Army, Dhahran, Saudi Arabia.

An unusually lively discussion followed each of the speakers, and all of the European, American and Indian doctors were generally interested in drawing on the experiences of one another in dealing with these conditions which are so prevalent around the Persian Gulf.

A motion was made at the end of the meeting that a Persian Gulf Medical Society be formed from which definite committees would be appointed for the study of the problems of the area, certain groups to be assigned one phase of a disease for investigation and final reports to be correlated later. The success of the meeting is evidenced from the fact that plans were made for the meeting to become a semiannual affair.

# Correspondence

## TONSILLECTOMY AND POLIOMYELITIS

*To the Editor:*—In a recent publication (*Laryngoscope* 58: 503, 1948), Dr. D. S. Cunning presented the results of a survey conducted by a committee of the American Laryngological, Rhinological and Otological Society on poliomyelitis and tonsillectomy for the year 1947 and also described the results of a similar survey for 1946. He summed up his conclusions as follows: "I am more than ever convinced that there is no causal relationship between the two, and that when a bulbar poliomyelitis follows a tonsillectomy it is coincidental."

This dangerous conclusion, which I fear is already being widely accepted by otorhinolaryngologists, should be very carefully weighed in the light of the evidence presented by the present report and of other evidence totally disregarded by it.

As regards the Cunning data, the following points deserve consideration. 1. Twenty-four cases of poliomyelitis in the reported series actually did follow tonsillectomy in 1947 and 62 cases in 1946. Of these 6, or 25 per cent, were bulbar in 1947, and 18, or 29 per cent, in 1946, whereas the incidence of bulbar poliomyelitis in all cases of poliomyelitis covered by the survey was 11.6 per cent in 1947 and 15.4 per cent in 1946; that is, the incidence of bulbar forms was slightly more than twice as high in persons for whom tonsillectomy has been done as in those for whom it has not. 2. Since the compilation by Aycock in 1942 (*Medicine* 21: 65, 1942) and the editorial of March 21, 1942 in The Journal (118: 980, 1942), tonsillectomy has come to be generally avoided during epidemics, and to a smaller extent even during the summer and fall months, because of the widespread fear of poliomyelitis that is felt both by physicians and laity; the result of such avoidance would, of course, be to reduce greatly the incidence of post-tonsillectomy cases and thus to increase the proportion of non-post-tonsillectomy cases. 3. The proof of a relationship between tonsillectomy and poliomyelitis is positive in respect to the high proportion of bulbar cases and cannot be blindly disregarded. Thus Aycock's summary shows 170 cases in which poliomyelitis followed tonsillectomy within thirty days (approximately the upper limit of incubation), of which 121, or 71 per cent, were bulbar, whereas in the thirty to sixty day period only 20 per cent were bulbar. The Cunning survey used a sixty day interval, which may explain the lower incidence of bulbar poliomyelitis than in the thirty day reports. The extraordinary report by Krill and Toomey (The Journal 117: 1013, 1941) deserves mention: Five children in one family were subjected to tonsillectomy on the same day, and all came down with bulbar poliomyelitis ten to twelve days later, 3 of them dying of the disease. Since the Aycock compilation, numerous other reports of post-tonsillectomy poliomyelitis have appeared (including the 86 of the two Cunning reports) and the 17 of Anderson's (*J. Pediat.* 27: 68, 1945) paper. The latter particularly should not be disregarded, since it offers clear proofs of the relationship under discussion. Anderson obtained data on tonsillectomies performed in Utah in 1943 both before and during the heavy epidemic of that year. Before (July) the outbreak the incidence of poliomyelitis after tonsillectomy was 0.7 per thousand; in August, when the epidemic began, it was 1.4 per thousand and at the height of the epidemic it was 19.2 per thousand tonsillectomies (these figures have been calculated from the original data). All the post-tonsillectomy cases of poliomyelitis were bulbar. The incidence of poliomyelitis in children in whom tonsillectomy had recently been done was 2.6 times, and of bulbar poliomyelitis 16 times greater than in the general child population.

The Cunning survey is therefore, in my opinion, a dangerous one, particularly since it is in a sense the official report of the American Laryngological, Rhinological and Otological Society and is apt to obtain wide acceptance, at least among specialists in that field, and might lead to the abandonment of what is now generally accepted as an important means of prevention of poliomyelitis. That the author himself still entertains doubts of the correctness of his views is indicated by a remark that follows the conclusion already quoted: "I do not advocate the indiscriminate removal of tonsils during any severe epidemic, and have no desire to place our children's lives in jeopardy through injudicious surgery. . . ." It is to be hoped that this sentiment will continue to be felt by all physicians who are responsible for deciding on tonsillectomy, especially during epidemics of poliomyelitis.

Harold K. Faber, M.D.,
Stanford University Hospital, San Francisco.

## HISTAMINE IN ARTERIOSCLEROSIS OBLITERANS

*To the Editor:*—In the December 4 issue of The Journal, page 1036, Friedell, Drucker and Pickett reported favorably on the treatment of arteriosclerosis obliterans with histidine and ascorbic acid. Good results from this therapy had previously been reported by Wirtschafter and Widmann, who suggested that the effects were due to the elaboration of histamine in vivo.

To test for the presence of significant amounts of circulating histamine, we studied gastric acid secretion following the administration of histidine and ascorbic acid in the doses recommended; gastric acidity was studied because, as shown by Hanson, Grossman and Ivy (*Am. J. Physiol.* 153: 243, 1948), the lowest threshold for definite histamine effect in man is on this function.

In 2 subjects there was no definite increase in the volume or acidity of the gastric juice over a three hour period. Six tests in dogs with gastric pouches also had negative results. We interpret these results to indicate that clinical results following treatment with histidine and ascorbic acid are probably not due to the formation of histamine in the body.

A. Littman, M.D.,
M. I. Grossman, M.D.,
University of Illinois, Chicago.

## BRITISH NATIONAL HEALTH ACT

*To the Editor:*—It is true that the comprehensive health service launched in this country on July 5 has many teething troubles, amongst them the great demand for medical services both in the hospital and in the consulting room. You are entitled to describe as folly the launching of such a service without sufficient personnel and premises. But the statement in The Journal of the American Medical Association of September 25 that "doctors are compelled to write formulas and prescriptions and reports many hours in advance of the time when they see the patients" is untrue. Indeed, it could be described as a libel on a profession which is proud of its traditions of service to its patients. May I ask that there be published in your journal, rightly famed for its scientific standards, an indication of the evidence for such an extraordinary statement?

Charles Hill, M.D., Secretary,
British Medical. Association,
Tavistock Square,
London W. C. 1, England.

Comment.—When this letter was received, a communication was sent to Dr. Charles Hill calling his attention to the fact that the Editor of The Journal had personally visited with general practitioners in England, one of whom had pointed to a pile of forms and who had definitely stated that he had spent two hours of the previous evening preparing these papers for the next day's practice. In reply Dr. Hill stated that he found it necessary to repeat his request for publication of his letter since "an issue of considerable importance to the British medical profession is involved." Since that time a mass of evidence has accumulated in the form of letters sent to the *British Medical Journal*, the London *Lancet* and important British newspapers, in which physicians who are working under the National Health Act have stated repeatedly that the paper work under the act is intolerable. There are so many forms to be filled out for so many different items and for so many different purposes that it is inconceivable that a British physician can carry on a competent medical practice without having the services of another person to do his paper work for him. The Journal expects to publish shortly an analysis of these data. Through the kindness of Dr. Wilson Jameson, who is chief medical officer of the British Ministry of Health, the headquarters of the American Medical Association has accumulated specimens of what appear to be merely a portion of the many forms used under the act.—Ed.

## THE CLINICAL USE OF FLUORESCEIN

*To the Editor:*—With reference to the recent article by Gerald J. Menaker and Morris L. Parker in the Dec. 4, 1948 number of The Journal, page 1039, it is pertinent to point out that many observers are finding a variety of uses for fluorescein in medicine.

Since 1946, fluorescein has been incorporated into several different technics at the University of Minnesota Hospitals. The most valuable among these has been a method of locating subcortical brain lesions. This procedure has been described in detail in the July 1948 issue of *The Journal of Neurosurgery*.

In addition to the use of the dye in the operating room, radioactive diiodofluorescein ($I^{131}$) has been employed in the attempt to locate tumors of the central nervous system preoperatively. This procedure was described in *Science* (107:569 [May 28] 1948) and in *Minnesota Medicine* (31:1073-1076 [Oct.] 1948).

In an attempt to make brain tumors radiopaque, other fluorescein compounds were synthesized. One of these dyes, tetraiodophthalic fluorescein, was rapidly concentrated by the gallbladder after excretion by the liver, which has led to its use in roentgen examination of the biliary tract (Intravenous Cholecystography with Tetraiodophthalic Fluorescein, *Surgery* 24:17 [July] 1948). It was observed that patients with certain types of hepatic disease did not concentrate the radioactive fluorescein in the liver as rapidly as was expected. This has stimulated further investigation along this line to see whether the radiofluorescein uptake of the diseased liver may be correlated with and used as an adjunct with other hepatic function tests. (Sussman, A. H., and Wang, J. C., unpublished data.)

Clinically, fluorescein has the following advantages: Its presence can be detected in minimal concentrations; it has a very low toxicity, and the coloration of the patient's skin is not marked or of long duration. The equipment required consists solely of the dye and a mercury arc lamp equipped with Wood's filter. One disadvantage of this technic is the fact that ultraviolet light penetrates but a fraction of a millimeter of tissue, and therefore its use is limited to direct examination of tissue surfaces and the lumens of organs covered by only a few layers of cells.

It would seem that the possible clinical and investigative uses of fluorescein are increasing rapidly, and will be limited only by the imagination of the investigator.

Samuel W. Hunter, M.D.,
Medical Fellow in Surgery, University of Minnesota
Medical School, Minneapolis.

# Medical Examinations and Licensure

## COMING EXAMINATIONS AND MEETINGS

### NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers, Feb., June and Sept. 1949. *Part II.* April 1949. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2, Pa.

### EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc.: *Written.* July 15. Various locations. Final date for filing application is April 15. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Avenue, New York 27.

American Board of Dermatology and Syphilology: *Written.* Various Centers, Feb. 17. *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: *Oral.* San Francisco, Feb. 8-10, 1949. New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17, 1949. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Written.* Jan. 14. *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston, Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: *Part I.* Various Centers, April and May. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: New York, May 11-14. Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April. Final date for filing application is March 1. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* St. Louis, Feb. 18-20. Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry and Neurology: *Oral.* May. Final date for filing application is Feb. 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, March 1949 Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

### BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Alaska:* Juneau, March 1. Sec.-Treas., Dr. W. M. Whitehead, Box 140, Juneau.

### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: Juneau, Feb. 21-26. Sec.-Treas., Dr. C. Earl Albrecht, Box 1731, Juneau.

Colorado: *Examination.* Denver, Mar. 2-3. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Connecticut: New Haven, Feb. 12. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

Florida: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Minnesota: *Examination.* April, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

Oklahoma: Spring of 1949. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, March 5 and June 18. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Rhode Island: *Examination.* Providence, Feb. 9. Chief, Mr. Thomas B. Casey, 366 State Office Building, Providence.

South Dakota: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

Tennessee: Memphis, March 21-22. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Wisconsin: Madison, April 2., Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

# Bureau of Legal Medicine and Legislation

## MEDICOLEGAL ABSTRACTS

**Governmental Hospitals: Validity of Rules Fixing Standards for Practitioners Therein.**—The plaintiff physician filed suit to restrain the defendant hospital from interfering with, or discriminating against, him in his right to practice and perform his professional duties in the hospital. From a judgment for the physician, the hospital appealed to the appellate court of Indiana.

On or about Sept. 9, 1947, the board of trustees of the Hamilton County Hospital adopted certain rules regulating the qualifications which a physician must possess in order to practice medicine, surgery and obstetrics in the hospital. Among others, it was provided that "the Resident Active Medical Staff, which shall include all the physicians having an unlimited license to practice medicine in the State of Indiana and having membership in Hamilton County professional organization of fully licensed physicians having the largest number of such physicians residing in Hamilton County" shall make up the membership of the Active Medical Staff of the hospital. Other rules provided that in order for a physician to practice in the hospital he either must be a member of this medical staff or must have a member of the medical staff associated with him in the treatment of his patient. The rules then went on to set forth the requirements of a surgeon desiring to practice surgery in the hospital but not being a member of the surgical staff as of March 1, 1947, as the defendant was not. Among other things, such a surgeon was required to "(*b*) have a certificate of internship showing one year service as an intern in a hospital approved by the Council of Medical Education and Hospitals of the American Medical Association. (*c*) In addition to intern training required under (*b*) he shall have had not less than three years of surgical training which meets the approval of the American College of Surgeons."

The plaintiff graduated from Indiana University School of Medicine in 1938 and practiced medicine in the state of Indiana from that time until June 1942, when he entered the army. While in the service he had a one month postgraduate course at Harvard University in general surgery and a three months' course in maxillofacial and plastic surgery at Columbia University. Later he was stationed in a 1,750 bed hospital at Camp Knox, where he served about three months in orthopedics, postoperative care, obstetrics, gyniatrics and general medicine. He was placed on the army inactive list in January 1945 and shortly thereafter opened an office in Louisville, where he was denied admission to the medical society and denied the right to practice in three of the Louisville hospitals. He testified that he had performed over three hundred major operations during his practice with 4 deaths. He admitted that he had never had any official intern training but expressed the opinion that his experience in the practice was far in excess of a year in intern training.

The plaintiff became a resident of Noblesville, Ind., about Jan. 1, 1947, and shortly thereafter applied for membership in the Hamilton County Medical Society, the organization referred to in the aforementioned rules. About Sept. 19, 1947, he was informed that his application for membership had been denied, and accordingly the hospital refused to permit him to treat his patients in it except in accordance with the provisions of the rules relating to having another physician on the staff associated with him.

It is undisputed, said the court, that the hospital would not permit the plaintiff to practice his profession in it except in accordance with the rules adopted. There was no evidence that these rules were unreasonable, arbitrary or unlawful. Nor was there any evidence to indicate that the Hamilton County Medical Society acted unlawfully, arbitrarily or capriciously in denying the plaintiff's application for membership nor that the society or the hospital were engaged in a conspiracy to prevent the plaintiff from engaging in the practice of his profession. There was, on the other hand, undisputed evidence from a number of physicians, surgeons and hospital authorities that these rules were reasonable and generally regarded as necessary to the proper conduct of hospitals; that such rules would be necessary for the protection of the public against the untrained surgeon who might undertake surgical services beyond his ability to perform. There was also evidence indicating the necessity of and the kind of special training generally required before a person is qualified or permitted to practice surgery. In the view we take of this case, the court of appeals continued, it is only necessary for us to determine whether or not these rules unlawfully and arbitrarily discriminated against the plaintiff.

The plaintiff contended that because of the provisions of section 22-3232, Burns' 1933 relating to county hospitals, the defendant hospital was prohibited from adopting the rules in question. This section provides:

> In the management of such public hospital, no discrimination shall be made against practitioners of any school of medicine recognized by the laws of Indiana, and all such legal practitioners shall have equal privileges in treating patients in said hospital. The patient shall have the absolute right to employ, at his or her own expense, his or her own physician, and, when acting for any patient in such hospital, the physician employed by such patient shall have exclusive charge of the care and treatment of such patient, and nurses therein shall, as to such patient, be subject to the directions of such physician; subject always to such general rules and regulations as shall be established by the board of trustees under the provisions of this act.

It seems clear to us, said the court, that this section provides, first, that there may be no discrimination against the practitioner of any school of medicine recognized by the laws of this state; second, that the patient shall have the right to employ his or her physician and such physician shall have the exclusive charge of the care and treatment of the patient, subject, however, to the general rules established by the board of trustees under the act authorizing the establishment of county hospitals. Section 10 of such act provides:

> Every hospital established under this act shall be for the benefit of the inhabitants of such county and of any person falling sick or being injured or maimed within its limits; . . . such hospital always being subject to such reasonable rules and regulations as said board may adopt in order to render the use of said hospital of the greatest benefit to the greatest number; and said board may exclude from the use of such hospital any and all inhabitants and persons who shall wilfully violate such rules and regulations. . . .

We are of the opinion, the court of appeals concluded, that this section provides ample authority for the adoption of the rules questioned by the plaintiff. In fact we are inclined to believe it places an obligation on such a board of trustees as the defendant to adopt reasonable rules and regulations to protect the public generally from unethical, unskilled and unscrupulous practitioners. Accordingly the judgment of the trial court in favor of the plaintiff physician was reversed.—*Hamilton County Hospital v. Andrews, 81 N. E. (2d) 699 (Ind., 1948).*

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

**Clinical Use of Triple Sulfonamide Mixture.**—Ledbetter and Cronheim say that the main interest in multiple sulfonamide therapy has centered around the reduction of renal complications, particularly crystalluria. The latter was present in 26 to 28 per cent when administering sulfadiazine or sulfamerazine alone. It can be reduced to 6 per cent when a combination of two drugs, sulfadiazine and sulfamerazine, is used, and it can be further reduced to below 3 per cent when adequate amounts of systemic alkalizers are added. The authors have extended their investigation of multiple sulfonamide therapy to the use of a mixture consisting of sulfadiazine, sulfamerazine and sulfathiazole without alkalizing salts. The preparation was composed of: sulfadiazine (microcrystalline), 3.5 per cent (weight/volume); sulfamerazine (microcrystalline), 3 per cent, and sulfathiazole (microcrystalline), 3.5 per cent, in an aromatized aqueous suspension base. The preparation was given to 28 selected patients mostly patients undergoing surgical treatment who required sulfonamide therapy. The initial dose was from 20 to 40 cc., representing from 2 to 4 Gm. of total sulfonamide drugs followed by 10 cc., equivalent to 1 Gm., of total sulfonamide drugs every four hours. With this dose adequate blood levels were maintained. The incidence of crystalluria was extremely low even though no alkali was administered. In no case was it necessary to discontinue drug treatment. The acetylation of the sulfonamide compounds in both blood and urine seems to be noticeably reduced.

**Cholesterol Metabolism in Coronary Thrombosis.**—According to Morrison and his associates the role of fat in the diet has recently aroused widespread interest as to its effect in producing atherosclerosis, arteriosclerosis and coronary artery disease. Contradictory reports exist. Some investigators report hypercholesteremia in these diseases and others report normal blood cholesterol levels. The authors believe that these discrepancies may be accounted for by differences in technical procedures, sex and age variations, uncontrolled dietary habits during the study and clinical diagnosis of the disease subject to variability in interpretations. The authors studied a consecutive unselected series of 200 patients with acute coronary occlusion for blood cholesterol and cholesterol ester levels within forty-eight hours after hospital admission. In 68 per cent of 73 patients under 60 years of age with proved acute coronary occlusion hypercholesterolemia was present. In 52 per cent of 125 patients over 60 years of age with proved acute coronary occlusion a normal cholesterol level was found. The authors conclude that coronary thrombosis in patients under the age of 60 is frequently associated with hypercholesterolemia and disturbances of cholesterol metabolism.

**Amyloidosis in Rheumatoid Arthritis.**—Unger and his associates point out that amyloidosis complicating rheumatoid arthritis was considered uncommon, but that there is reason to believe that the two conditions coexist more frequently. The fact that simultaneous occurrence was usually discovered at necropsy indicates a lack of awareness of the association. The authors examined the records of 58 patients with rheumatoid arthritis who came to necropsy. There were 4 cases in which amyloidosis could not be attributed to causes other than rheumatoid arthritis. Despite the presence of suggestive clinical evidence of amyloidosis, the Congo red test had not been performed in these cases, since the diagnosis was not suspected ante mortem. The postmortem examination showed amyloidosis of varying severity and distribution, involving liver, spleen and kidney in every case and, in addition, in 1 case the adrenals, pancreas and heart. The authors searched for amyloidosis among 56 living patients with rheumatoid arthritis and found it in 6. Five of the 6 showed Congo red absorption ranging from 86 to 100 per cent one hour after injection. In the remaining case, 81 per cent of the injected dye was removed after one hour. It appears certain that amyloidosis was secondary to rheumatoid arthritis in 5 of the 6 cases. Albuminuria of varying degree was present in all of the patients. Of great interest was the low serum amino acid levels in all living patients. Earlier recognition of amyloidosis would permit testing the efficacy of the recently recommended therapeutic regimen of desiccated whole liver powder.

**Abnormal Electrocardiograms in Absence of Heart Disease.**—Littmann describes 9 instances of gross electrocardiographic abnormalities, largely concerned with precordial T waves, in persons without demonstrable heart disease. They were found over a period of approximately eighteen months during which time some 5,000 electrocardiograms were read. With 1 exception, these persons had no complaints referable to the heart. In that case the symptoms were considered to be due to cardiac neurosis and aerophagia. Essentially normal curves were eventually obtained in most of the subjects. The cause for the anomalies was demonstrated in several of the patients but remained obscure in the remainder. Littmann suggests that when abnormal curves are encountered without adequate support of additional findings, the following extensions of electrocardiographic technic should be made: (1) electrocardiograms with multiple chest leads employing the several standard indifferent points; (2) tracings recorded with the patient in various positions; (3) tracings made at various hours of the day, before and after meals; (4) curves obtained before and after exercise, and (5) serial tracings made over a period of weeks or months.

**Electrocardiographic Changes in Rheumatic Fever.**—On the basis of illustrative cases Sokolow presents a critical appraisal of the value and limitation of electrocardiography in the diagnosis of rheumatic carditis. Cardiac enlargement, pericarditis, cardiac failure, diastolic murmurs and unequivocally significant systolic murmurs are relatively infrequent in young adults with rheumatic fever, but abnormalities in the electrocardiogram are the most frequent criteria of carditis. The most common abnormality in the electrocardiogram in rheumatic fever is a partial auriculoventricular block. This is present in 60 per cent of patients who show electrocardiographic abnormalities. Inversion of $T_1$, $T_2$ or $T_4$, alone or in combination, represents the second most frequent abnormality, being found in 35 per cent of those patients in whom electrocardiographic abnormalities are present. Abnormalities in the electrocardiogram other than conduction defects, S-T and T wave changes and major arrhythmias occur. Care must be exercised before interpreting them as indicative of active carditis when they are present as the only abnormal electrocardiographic finding in a single tracing. Serial tests may permit proper interpretation. The electrocardiogram may reveal the polycyclic nature of the course of rheumatic fever in the absence of clinical evidence of polycyclic activity. This indicates the necessity of taking electrocardiograms early and frequently. Abnormalities in the electrocardiogram may indicate reactivation of the rheumatic process during convalescence when the patient is first allowed some physical activity. It is possible also that carditis presents clinical manifestations and yet presents no electrocardiographic abnormalities.

**Treatment of Pregnant Syphilitic Women.**—Goodwin and Farber observed 363 women with varying types of syphilitic infection of three months' to forty years' duration who previously received metal chemotherapy through 570 subsequent pregnancies in which further antisyphilitic treatment was purposely omitted. Twenty-two women, all of whom were originally treated with penicillin for early syphilis, were observed through 26 subsequent pregnancies in which further antisyphilitic treatment was purposely omitted. Of the 596 infants born of these pregnancies during which the mothers were not treated, 548 (92 per cent) were born alive. Twenty of the 48 infants stillborn or miscarried were examined at necropsy. Evidence of syphilis in the fetus was found in none. Of the 548 infants born alive 458 were followed for more than two months after birth; 257 were followed for more than a year and 141 for more than three years. All of these children are normal and nonsyphilitic. These data indicate that it is not necessary to administer antisyphilitic treatment to a syphilitic woman during every pregnancy and that there is a high degree of probability that the infant will be normal if maternal treatment is withheld, provided that the mother has previously received 4.0 Gm. or more of arsphenamine together with concomitant bismuth compound, or 2,400,000 units or more of penicillin, that she shows no clinical signs of active syphilitic infection and that her blood serologic tests for syphilis are negative in result or, if still seropositive, in low titer only (1 to 8 dilution units). A syphilitic woman should be further treated in any pregnancy in which she herself shows clinical evidence of active syphilitic infection or in which, in the absence of such evidence, she herself has a positive blood serologic reaction for syphilis in a quantitative titer of 16 or more dilution units.

**Procaine Penicillin G in Gonorrhea.**—Tucker and his co-workers treated 39 men and 11 women with uncomplicated acute gonococcic cervicitis or urethritis by single intramuscular gravimetric injections of crystalline procaine penicillin G in sesame oil containing either 100, 125, 175, 250 or 500 units (0.1 to 0.5 mg.) per kilogram of body weight. Serums and urine specimens were taken at appropriate intervals and assayed for penicillin activity. Cultures and smears for Neisseria gonorrheae were obtained before treatment and three, six, twenty-four and forty-eight hours after the injection. Patients clinically well and bacteriologically negative at the forty-eight hour period were considered cured. Serum concentrations of penicillin G were proportional to the dosages given one hour after treatment and subsequently. Percentage cumulative recovery of penicillin, in the urine was approximately the same over the 2.5 fold dosage range studied. A dosage of 100 units per kilogram failed consistently to cure. The amount of procaine penicillin G which cured one half the patients treated was approximately 175 units per kilogram. All patients who were given 250 units per kilogram of body weight attained clinical and bacteriologic cure by the forty-eighth hour. Since the entire range from cure to obvious clinical failure embraced only a 2.5 fold increase in dosage and since the practicing physician or clinic director is not interested in the "minimal curative dosage" but in the smallest dosage which may be relied on to cure consistently uncomplicated acute gonorrhea, a routine therapeutic dosage of 0.5 mg. per kilogram may be recommended. For the average adult this would represent approximately 0.12 cc. of the 300,000 units per cubic centimeter concentration of procaine penicillin G.

**Treatment of Neurosyphilis with Malaria and Penicillin.**—Kierland and his co-workers treated 76 patients, 59 men and 17 women, the majority of whom were aged 40 or more, who had severe neurosyphilis, with a combined course of malaria and penicillin. Spinal fluid examinations reveal that 40 of the 76 patients had the most active and abnormal fluids before treatment, while 1 patient was classified similarly when last examined. "Arrested" type of spinal fluids was observed in 4 patients before malaria-penicillin treatment, while 48 patients had similar findings after treatment. Sixty-seven patients had minimal abnormalities, arrested condition or normal fluids after treatment. In general a higher percentage of paretic patients had abnormal reactions following treatment than of any other group. Three patients had a relapse in the cell count after an initial return to normal. The clinical response was satisfactory in 44 of the 63 patients who had symptomatic neurosyphilis before treatment, and 4 of these 63 patients were clinically worse than before treatment. Only 3 of 7 patients with symptomatic optic atrophy had some improvement of vision, while 28 of 35 patients with symptomatic paresis and taboparesis had satisfactory clinical responses. The lapse of time seemed to improve the clinical results. Part of this apparent improvement with longer period of observation after treatment is due to the selection of some cases earlier for further treatment because of incomplete response to initial therapy. Combination of malaria and penicillin is the treatment of choice in severe parenchymatous types of neurosyphilis. Patients with the milder forms of neurosyphilis, such as asymptomatic and meningeal syphilis, may first be given the advantage of one or two courses of penicillin alone.

**Streptomycin Treatment of Tuberculous Sinuses.**—Brock treated 12 patients with a total of sixty draining cutaneous tuberculous sinuses by intramuscular administration of 1.8 Gm. of streptomycin daily in divided doses of 0.3 Gm. every four hours. Six of the patients received treatment for ninety days; the remainder were treated for one hundred and fifty days with an interruption of three weeks after the first ninety days. Headache and dizziness were observed rather regularly; 3 patients had a febrile reaction shortly after the administration of the drug and 4 patients showed eosinophilia (over 5 per cent) which persisted throughout the treatment. None of these toxic reactions was severe enough to justify discontinuance of the drug. Soon after the start of the treatment 11 of the 12 patients showed clinical signs of improvement manifested by a sense of well-being, increase in appetite and gain in weight. Nine of the sixty sinuses closed within one to four weeks, and nine within six to eight weeks, after streptomycin therapy was started. Thirty sinuses closed between the tenth and the twelfth week of treatment and 11 closed within thirteen to twenty weeks of the start of treatment. Closure was more prompt when free drainage was present. Of the sixty original draining sinuses only one continues to drain eight months since streptomycin was started, but even this sinus is showing definite improvement. The series has not been followed for a sufficient period to determine whether streptomycin has produced a permanent closure of the sinuses, but the promptness with which they healed following initiation of treatment was outstanding.

**Community Survey on Tuberculosis Morbidity.**—Davies and his co-workers made a complete community roentgenologic survey for tuberculosis in Ely, Minn., a village of approximately 6,000 persons, and the surrounding rural area in 1943. Of the 5,672 persons with roentgenograms of the chest which were considered negative for reinfection type tuberculosis in 1943, 4,206 were reexamined in 1946 and were again found to have negative roentgenograms. No one in Ely the roentgenogram of whose chest was negative for reinfection tuberculosis in 1943 has been demonstrated to have contracted the disease since. One hundred and eight (72 per cent) of the 149 persons who had evidence of apparently inactive tuberculosis in 1943 were reexamined in 1946 and showed no significant change in the observations. The fact that, of the 41 persons not reexamined in 1946, 15 had had recent satisfactory roentgenograms of the chest, 11 had moved away from the community and only 9 who remained in the community were not reexamined, chiefly because they were uncooperative, is a rough measure of the adequacy of the follow-up program. Fourteen persons were classified as having had active or suspected active tuberculosis in 1943. In the 1946 survey, 6 persons (0.09 per cent of the population) were classified as having active or suspected active tuberculosis. The survey, which included examination of a high percentage of the population, hospitalization of patients with active disease and adequate follow-up examination of those with apparently inactive disease, has been followed by a sharp drop in the incidence of new cases of tuberculosis. This is the second time such a result has been demonstrated. A community survey of this type is a practicable method of tuberculosis control. In the community studied, most cases of clinical pulmonary tuberculosis which have occurred in recent years have apparently been the result of recent exogenous infection.

**Pathology of Reinfection.**—Pagel and Toussaint define reinfection as a tuberculous infection occurring in a person in whom a previous primary infection is anatomically healed. In the diagnosis of reinfection in tuberculosis sources of error may arise. Four cases of apparently recent changes of endogenous origin from an obsolete lesion in 2 male and 2 female patients between the ages of 6½ and 54 years are reported, illustrating the fallacy of the argument that obsolescence and ossification exclude a lesion as the original source of still fresh and progressive tuberculous changes. Three cases of long persistence of the "soft state" of the focus at the site of entry of the tubercle bacilli or of the homologous caseous focus in the regional lymph nodes or in both constituents of the primary complex in 3 women and 1 man between the ages of 17 and 43 are reported which demonstrate that decided differences in quality between two foci—firmly calcified as against caseous—do not exclude their being closely related to each other; these differences do not provide evidence in themselves that the fresh looking lesion is due to new infection from without. Consequently, delayed calcification of both parts or synchronous calcification of one constituent of the primary complex may be another sourse of erroneous diagnosis. One case in a man aged 25 is presented in which a cavity healed at the time of observation after having given rise to bronchogenic phthisis. The clinical and postmortem roentgenograms closely simulated reinfection, which was only disproved by microscopic examination of the hilar lymph nodes.

**Urinary Excretion of Radioactive Iodine in Hyperthyroidism.**—McArthur and her associates attempted to evaluate the clinical usefulness of the measurement of radioactive iodine excretion by defining more precisely the range of excretion to be anticipated in nonthyrotoxic persons and in patients with hyperthyroidism. Tracer doses (2 to 160 micrograms) of sodium iodide labeled with radioactive iodine ($I^{131}$) the specific activity of which varied from 50 to 2,000 microcuries (in the majority of instances the activity was 100 microcuries) were administered orally to patients. Urine was collected for forty-eight hours following the administration of the labeled iodine, and the percentage excretion determined from the specific activity of an aliquot. The mean urinary excretion of radioactive iodine by 22 thyrotoxic patients was 25 per cent, range 7 per cent to 45 per cent. The mean urinary excretion of radioactive iodine by 30 nonthyrotoxic patients was 60 per cent, range 23 per cent to 98 per cent. There is considerable overlapping in the radioactive iodine excretion between thyrotoxic and nonthyrotoxic persons in the range 20 to 40 per cent. The finding of a low urinary excretion of radioactive iodine aided in establishing the diagnosis of Graves' disease in clinically equivocal cases. The finding of a high urinary excretion of radioactive iodine was of assistance in excluding Graves' disease in borderline cases in which a truly basal metabolic rate could not be obtained. Specifically, the exclusion of Graves' disease has been facilitated in patients exhibiting hypermetabolism due to alcoholism, anxiety, compensated hypertensive cardiovascular disease, parkinsonism, pheochromocytoma and thyrotoxicosis factitia. In that group of patients exhibiting an intermediate (20 to 40 per cent) excretion of radioactive iodine, the diagnosis of Graves' disease must be established by other clinical and laboratory findings. Search for external gamma radiation with the Geiger-Müller counter following the administration of a tracer dose of radioactive iodine enables the location of thyroid tissue to be established when doubt exists.

**Pathogenesis of Human Brucellosis.**—According to Spink there are indications that brucellosis is on the increase both in domestic animals and in human beings. Human brucellosis is a major problem in public health in some sections of this country. The reservoir of the disease resides in domestic animals, especially cattle, swine and goats. The disease is transmitted either directly or indirectly to human beings from infected animals, and rarely, if at all, from human being to human being. Intracellular parasitism results from the invasion of tissues by Brucella resulting in the characteristic, but not specific, tissue reaction of proliferation of epithelioid cells and giant cells. Complications include destructive osseous lesions, subacute bacterial endocarditis, encephalitis and grossly suppurative lesions. Hypersensitivity of the tissues to an antigen or antigens of Brucella is a constant feature of brucellosis, and the symptom complex of the disease may depend, in part at least, on this state of hypersensitivity. The most satisfactory treatment to date for both acute and chronic cases of brucellosis is a combination of streptomycin and sulfadiazine. Thus far, 17 patients have been treated with a maximum follow-up period of one year. The clinical course of brucellosis is shortened by this combined therapy. The combination is effective against such complications of brucellosis as subacute bacterial endocarditis and spondylitis. Optimum doses remain to be worked out, but at present it is recommended that 0.5 Gm. streptomycin be given intramuscularly every six hours for two weeks. At the same time that therapy with streptomycin is started, 3 to 4 Gm. of sulfadiazine should be administered orally, and then 1 Gm. every four hours for a total of two weeks. The ultimate elimination of human brucellosis depends on eradicating the disease from domestic animals.

**Acute Mercury Poisoning.**—Batson and Peterson present the history of a patient with severe mercury poisoning who was treated with BAL (2,3-dimercaptopropanol) and whose prolonged anuria was combated successfully by peritoneal irrigation. BAL should be administered immediately, preferably in the emergency room or home, to patients who are suspected of *having ingested bichloride of mercury. The initial injection* should be 3.5 to 4.5 mg. per kilogram of body weight followed in two hours by 2 to 3 mg. per kilogram and at intervals of six hours by four additional doses of 2 to 3 mg. per kilogram. *Thereafter one should administer 2 to 3 mg. per kilogram* twice daily until all evidence of poisoning has disappeared. Gastric lavage should be carried out immediately. Four per cent *sodium bicarbonate solution is probably as effective as any other solution in the removal of excess mercury.* Colonic flushings should be done approximately twice daily. In cases of severe poisoning every effort should be made to prevent shock. This requires administration of whole blood, plasma and crystalloid solutions. The fluid and electrolyte balance should be maintained and dehydration or edema should be prevented. Frequent determinations of blood nonprotein nitrogen, plasma carbon dioxide–combining power, plasma proteins, plasma chloride and hemoglobin are necessary in adjusting the regimen. In patients who are anuric, peritoneal irrigation may effectively remove metabolic wastes until renal function returns.

**Pure Serum Albumin or Plasma in Chronic Hypoalbuminemia.**—Comparable injections of twice concentrated plasma and of 25 per cent salt-poor human albumin were studied by Elman and his associates in 22 patients with various diseases having in common malnutrition and hypoalbuminemia. Both solutions caused an immediate and similar increase in albumin concentration, in total circulating albumin and in plasma volume. However, significant differences were apparent within twenty-four hours. The concentration of albumin was more sustained with the solution of pure albumin than with plasma. Pure albumin produced no increase in venous pressure, whereas plasma did, particularly when a reaction occurred. No reactions occurred with albumin in contrast to their frequency with plasma. The pure albumin solution was more effective than plasma in inducing diuresis with weight loss and relief of edema. Solutions of 25 per cent salt-poor albumin would seem to be far superior to plasma in the treatment of nutritional hypoalbuminemia.

**Strangulated Diaphragmatic Hernia.**—Carter and Giuseffi had their attention drawn to strangulated diaphragmatic hernia by observations on 2 cases observed within one year. They were able to collect 39 cases of strangulated diaphragmatic hernia, to which they added 4 cases from the Cincinnati General Hospital. Diaphragmatic hernias have been classified as congenital, acquired and traumatic types. *Strangulation is most frequent* in the traumatic type. Of the 43 cases with strangulation 34 were traumatic. Traumatic diaphragmatic hernia showed an increased incidence during and immediately after the first world war, *and will undoubtedly show a similar tendency after the* recent conflict. The following should suggest the diagnosis of a strangulated diaphragmatic hernia: (1) signs of acute gastrointestinal obstruction; (2) a history of an old injury; *(3) physical findings referable to the left side of the thorax,* particularly cardiac shift to the right and, on occasion, bloody fluid on aspiration, and (4) roentgenologic evidence of a high *left diaphragm. The treatment of strangulated diaphragmatic hernia is emergency surgery.* The advisability of utilizing the transthoracic route is emphasized. Such an approach is especially suited for small hernias since it allows the operator to investigate the diaphragm under excellent visual conditions. When there is no strangulation of the viscera the incision is adequate for the reduction of the organs and successful repair of the hernia. When a large amount of viscera has been strangulated the thoracic incision should be extended across the costal margin into the abdomen.

**Effect of High Altitudes on Central Nervous System.**—Masland says that during the course of altitude training neurologic reactions have been observed in an altitude chamber. Symptoms tend to develop in two phases. The first, or "primary," reaction occurs during decompression or immediately after return to normal atmospheric pressure. These symptoms are usually transitory and mild. The second, or "delayed," phase of the reaction develops from two to twelve hours after "descent," at a time when the subject may have appeared completely recovered from the early symptoms of his experience. The delayed symptoms are often persistent and severe. A given subject may show only a "primary" reaction or only a "delayed" reaction, or both. Case reports to illustrate these reactions are presented. The primary type of reaction is due to the lodgment of air bubbles within the cerebral vessels. It is possible that vasospasm resulting from the lodgment of the bubble may be an additional factor in the development of symptoms. The delayed reaction is also vascular in origin and results from a change in permeability of the vascular wall secondary to its occlusion during the flight. On the disappearance of bubbles after descent the damaged vessels become dilated; the blood is stagnant and the walls are permeable. Leakage of fluid results in cerebral edema and diffuse disturbance of cerebral function. Symptoms usually progress slowly over a period of two to twenty-four hours from a circumscribed paresis, or moderate intellectual impairment with confusion, to severe paralysis and deep coma. The symptoms remain at their peak for twenty-four to thirty hours; then, if recovery is to take place, they gradually regress. In fatal cases, death has occurred from thirty-nine to seventy hours after the onset of symptoms. At necropsy flattening of the convolutions, a gelatinous exudate and, occasionally, small hemorrhages are noted. Aring has described under the term "vasoparalysis" a similar reaction of the cerebral vessels following embolism. It is thus probable that the delayed neurologic reaction represents a form of cerebral edema, comparable to the pulmonary edema seen in the late "shock" reaction, and resulting from capillary and tissue injury caused by cerebral aeroembolism and vasospasm at the time of flight.

**Sleep-Electroshock Therapy.**—Rubinstein points out that soon after the introduction of electroshock treatment it became apparent that this method was inapplicable to a number of patients who might otherwise have been expected to profit from such treatment. Such patients include those who have acquired a fear of the treatment and those who react to electroshock with psychomotor irritability. *It is the purpose of this communication* to describe the method whereby both these difficulties were successfully circumvented. The method consists in the intravenous injection of 2.5 to 5 per cent thiopental sodium prior to the application of the electric current. No complications have been observed in the course of over five hundred treatments. On the contrary, by the careful gaging of the depth of anesthesia, one may selectively evoke minor, medium or major reactions.

**Tyrothricin as Antibiotic.**—Lask treated locally with tyrothricin 10 patients who had granulating wounds, in preparation for skin grafts. Cultures of material from the wounds were made at frequent intervals. Streptococci were rapidly eliminated. In 1 case the granulating area resulting from a burn measured approximately 40 per cent of the total surface. Tyrothricin was applied every day over the total area for approximately one month with no toxic effect. In addition, a series of 15 patients with chronic ulcers of the leg were treated by local application of tyrothricin. The cause of the lesion in 14 of the patients was thrombophlebitis; in 1 it was trauma. All patients were given ambulatory treatment. Healing took place in 9 patients within four to twelve weeks, although recurrence developed in 2. It was noted that when Pseudomonas bacilli were present in large numbers the tyrothricin was inhibited and healing was retarded. In a patient with bilateral ulcers one side was treated with tyrothricin solution and the other with boric acid solution. In spite of the fact that tyrothricin was used on the larger ulcer, the gram-postive bacterial flora was immensely reduced on this side and healing was much faster. Subsequently tyrothricin was used on the ulcer which was treated initially with boric acid: the bacterial flora was immediately altered and healing progressed more satisfactorily. Experiments on white mice and guinea pigs showed conclusively that tyrothricin will not protect an animal from peritonitis due to Clostridium welchii or Escherichia coli. Tyrothricin is extremely toxic and hemolytic; the parenteral route is dangerous. *It should be used only topically and against organisms of the gram-positive variety.* Except for these limitations, it is one of the most effective agents available.

**Streptomycin for Peritonitis.**—Morton and Smith instilled streptomycin in 1 Gm. doses daily in 6 selected cases of localized infections of the peritoneal cavity. Patient 1 had a perforated common bile duct causing subphrenic abscess; choledocholithotomy was performed and after that penicillin was used unsuccessfully because of the continued culture of Bacillus coli, which was producing penicillinase. Streptomycin instilled into the abscess on four occasions resulted in the disappearance of Bacillus coli. Penicillin was then used locally for the still persisting gram-postive organisms and resulted in a gratifying clinical cure. This case illustrates the importance of the order and the correct timing of adequate surgical treatment combined with the use of antibiotics. In patient 2 with a subphrenic abscess as a sequela of perforated gastric ulcer, penicillin and surgical drainage failed. After the instillation of streptomycin into the abscess cavity daily for four days the temperature became normal; the patient has remained well. In patient 3 with a subphrenic abscess after perforation of a duodenal stump subsequent to partial gastrectomy, streptomycin was not successful even though a single usually susceptible organism was present. In patient 4 with a perforated appendix and localized abscess in the pelvis and in the right lower part of the abdomen a single dose of streptomycin was sufficient, and the patient herself felt improvement within twelve hours. In patient 5 with acute appendicitis, with perforation and general peritonitis and pyelophlebitis penicillin was used first postoperatively for one week but failed. A culture yielded mainly Bacillus coli. Streptomycin was instilled into the cavity and after the second dose the culture remained sterile. The patient died of hepatic insufficiency on the tenth postoperative day. This case illustrates failure in timing. *The vicious cycle of toxemia was never broken.* In case 6 colectomy was performed on an exceedingly debilitated patient with ulcerative colitis, multiple polyposis and localized peritonitis. He was given penicillin, and streptomycin was instilled into the peritoneal cavity. In spite of the continued presence of intestinal organisms the patient made steady improvement and had no more than the usual reactionary temperature from such a major procedure. Streptomycin used either alone or in combination with penicillin might achieve considerable importance because of the penicillin-insensitive coliform bacteria. Penicillin remains the drug of choice for gram-positive bacteria.

**Chronic Infectious Mononucleosis.**—Isaacs says that in a group of 206 patients with infectious mononucleosis, 53 had some symptoms which persisted for three months to at least four years or longer. The syndrome included ease of fatigue, exhaustion, aching of the legs, weakness, depression, afternoon elevation of temperature (99.8 to 101 F.), moderate splenomegaly, low blood pressure, low blood sugar, often low specific gravity of the urine, and the presence of infectious mononucleosis cells in the blood. The 53 patients with the chronic symptoms included 22 males and 31 females. The ages ranged from 8 months to 60 years. These patients had been sent in for study, with possible diagnoses of undulent fever, tuberculosis, Addison's disease, Hodgkin's disease, Rocky Mountain spotted fever, lymphosarcoma, hypothyroidism, menopausal syndrome, subacute bacterial endocarditis, neurasthenia and syphilis. All of the group showed infectious mononucleosis cells in the blood. In no case of the chronic group was the sheep cell (heterophil) agglutination titer above 1:64. In 3 of the group characteristics of lymphoblastoma developed and 2 showed the features of Banti's congestive splenomegaly. The symptoms responded to treatment with a preparation of adrenal cortical extract. The syndrome is apparently not uncommon and the intense, prolonged debility, together with the definite improvement after therapy with adrenal cortical extract, makes its recognition of great practical importance.

**Urethane Therapy in Leukemia.**—Creskoff and his co-workers report the results of urethane therapy in 24 patients with leukemia. The average daily dose was 4 Gm. orally or intravenously. The drug is irregularly effective. Chronic myelogenous leukemia appears more responsive than the lymphatic variety. Acute leukemias are not significantly altered in course by urethane. Urethane produces a fall in the total leukocyte count in a majority of all types of leukemia. Clinical improvement does not necessarily follow. Nausea is the most frequent side effect of urethane therapy. Possible marrow aplasia is the most dangerous toxic effect. Urethane is of definite, but limited value in the treatment of chronic leukemia. In some instances it compares favorably with roentgen therapy, but, in general, it is less dependable, particularly in its frequent failure to induce optimum return of normal red cell and platelet values and optimum regression of organ infiltration.

**Clinical Use of Radioactive Iodine.**—Werner and his associates used radioactive iodine of 8-day half life ($I^{131}$) in tracer studies of iodine uptake by normal and disordered thyroid glands and in the treatment of 40 cases of toxic goiter. Tracer uptake has diagnostic value when stable iodine or antithyroid drugs have not been given shortly before this procedure. Normal uptake is 20 to 30 per cent of the administered tracer dose of 50 to 75 uc. (microcuries per gram of estimated gland weight). Anything more than 40 per cent is regarded as definitely hyperthyroid; anything less than 10 per cent as hypothyroid. Therapy has been successful in 30 of 34 cases after one or, when necessary, two doses. In the other 4 it was a failure. Six other patients who were treated did not respond to one dose, and have not been followed after a second long enough to draw conclusions. The causes of failure in the present series appear to be due to inadequate dosage, related mainly to the size of the gland. It is possible that an unusually high basal metabolic rate may also contribute to an unsatisfactory result. The complications following radioiodine therapy include sore throat, cough, tender gland, flare-up of toxicity and transient hypothyroidism. Only a few cases of each have been observed; none of them was serious. Radiation hazards attendant on this therapy are unimportant under present conditions.

Clinical Application of British Anti-Lewisite. J. A. Luetscher Jr.—p. 491.

***Anticoagulant Therapy in Thromboembolic Diseases.***—Wright practiced anticoagulant therapy in 46 complicated cases of coronary thrombosis and in 34 uncomplicated cases. In the 46 complicated cases there were 11 deaths. In the 34 uncomplicated cases there were 4 deaths. Although the series was so small that it was of no statistical significance, it appeared that "dicumarol" did not aggravate the condition in any patient. It appeared physiologically sound to give anticoagulant therapy when there was a tendency for propagation of a thrombus, when multiple thrombi formed in the coronary arteries or elsewhere, or when there were emboli. Thromboembolic processes appeared to have been interrupted and the rate and rhythm of the heart were not directly affected by "dicumarol." In a series the study of which is now in progress in sixteen hospitals, it is planned to include 1,000 cases. So far deaths apparently have been reduced one third and the thromboembolic complications one half by anticoagulant therapy, alternate cases being used as controls. Fourteen additional patients who had rheumatic fever followed by auricular fibrillation and years later have begun to have multiple emboli were started on anticoagulant therapy on a permanent basis. Of the 14 patients 2 failed to continue with it. The other 12 who were maintained on the therapy have now gone approximately nine years without an embolism of any kind. Although the group is small, the patients present a condition for which formerly one had nothing to offer but hope that another embolus would not occur.

World Health Assembly—Geneva 1948: Notes by an Amateur in Public Health. J. R. Miller.—p. 849.

**Dangers of Hyperpyrexia: Typhoid Vaccine.**—Bellach believes that the hyperpyrexia produced by the intravenous injection of typhoid vaccine has held a well deserved place in the treatment of a variety of diseases. Although unfavorable reactions are relatively rare, they may occasionally be severe enough to be a serious threat to the patient. The dosage of typhoid vaccine does not appear to be a major factor in determining the incidence of untoward reactions. Severe and fatal complications have followed the administration of minute doses, while large ones have been used without incident. The vaccine used by the dermatologic services of the New York Post-Graduate Hospital contains 1,000,000,000 Eberthella typhi, 750,000,000 Salmonella paratyphi and 750,000,000 Salmonella schotmuelleri, or total dosage of 2,500,000,000 micro-organisms per cubic centimeter. The initial dose is 0.1 cc., or 250,000,000 micro-organisms; it is given in the morning on an empty stomach, and food and fluids are withheld until the temperature reaches its peak. If the rise exceeds 105 F., it is interrupted by forcing the intake of fluids, administration of acetylsalicylic acid and the application of cold packs. If the preceding bout of hyperpyrexia has been well tolerated, the injection is repeated every third day with increments in dosage according to the patient's tolerance. The author presents the case of a man, aged 27, in whom treatment with typhoid vaccine resulted in an unusually severe reaction. Recovery in this case was complete and may have been aided by the prompt institution of adequate therapy for the shocklike and hypotensive reaction. The author considers it advisable that all patients receiving intravenous typhoid vaccine therapy be hospitalized so that any untoward reactions may be recognized and treated promptly. All patients should be studied adequately to discover any existing pathologic states which would contraindicate the use of typhoid vaccine or which might themselves be adversely affected by its administration.

*Antithyroid Effect of Certain Foods in Man as Determined with Radioactive Iodine. M. A. Greer and E. B. Astwood.—p. 105.

**Antithyroid Effect of Certain Foods.**—Greer and Astwood direct attention to the discovery by Chesney and others in 1928 of the goitrogenic effect of cabbage in a colony of rabbits. Determination of antithyroid activity by observing the inhibition of the radioactive iodine uptake will provide a rapid and convenient method for assaying the effect of various foods in man. The authors report studies on 100 persons with sixty-one different types of foods. A tracer dose of 100 microcuries of radioactive $I^{131}$ in 10 cc. of isotonic sodium chloride solution was given by mouth in the morning, the breakfast having been omitted. The uptake of radioactive iodine by the thyroid was then determined with a Geiger-Müller counter. Counts were taken about every fifteen minutes until the course of the uptake seemed to be fairly well established. This usually required sixty to ninety minutes. The subject was then given the food to be assayed. After completion of the test meal, the subjects returned for counts at one hour intervals. Of the foods tested rutabaga was found to possess the greatest antithyroid activity. Vegetables were more active than animal products and the most potent vegetable families were the Chenopodiaceae such as beets and spinach; the Compositae (lettuce); the Cruciferae, that is, various vegetables of the cabbage family including the rutabaga; the Cupuliferae (filberts); the Juglandaceae (walnuts); the Leguminosae such as beans, peas and peanuts; the Rosaceae including apples, pears, apricots, blackberries, raspberries and strawberries, and the Umbelliferae such as carrots and celery. Cow's milk, beef liver and oysters also showed some antithyroid activity. Since there are many persons who habitually consume considerable amounts of foods that have been found to possess antithyroid activity and in whom goiters do not develop, great variation in the response to goitrogenic stimuli probably exists.

**Evaluation of Therapeutic Results in Fatty Cirrhosis.**—Volwiler and his associates define fatty cirrhosis as the progressive degenerative hepatitis commonly associated with malnutrition and the excessive intake of alcohol. They believe that what has ordinarily been called portal cirrhosis can be divided into two types: toxic or postatrophy cirrhosis and fatty or Laennec's cirrhosis. This paper deals only with cases of the latter type, which in New England is usually seen in patients with a history of severe alcoholism combined with a faulty dietary intake. The discussion emphasizes the advantages of a threefold criterion for assessing the results of specific treatment in fatty cirrhosis. Comparison has been made of clinical, laboratory and histologic findings before and after a period of a given form of treatment in 13 patients, selected as being similar from the point of view of clinical findings and histologic pattern of the hepatic tissue. The authors believe that the lack of numbers in their studies is offset by the fact that the patients were more accurately selected and more completely studied under controlled conditions than were those previously reported by other investigators. Only those patients who were in a similar histologic phase of fatty cirrhosis, as judged from the initial trocar liver biopsy, were selected for comparison; serial liver biopsies were obtained in all the patients. The livers of all patients improved at the same rate. The features common to the treatment of all patients were rest, the insistence on eating and the provision of a daily protein intake of 100 Gm. or more. Whether the amount of dietary fat given was high or low, no difference in the rate of disappearance of fat vacuolization or in the speed of hepatic repair was found. The authors believe that the addition of lipotropic agents and/or vitamins to an adequate food intake is unnecessary and does not increase the rate of improvement. Their observations suggest two other points: (1) that the ingestion of lipotropes or vitamins will never substitute for a proper diet as protection against the development of fatty cirrhosis, and (2) that a moderate alcohol intake will not prevent satisfactory repair of liver damage in fatty cirrhosis, provided that the dietary intake is ample and well balanced.

Appendiceal Lithiasis. B. F. Hoopes.—p. 192.

**Cholesterol–Basal Metabolism Determinations.**—Hutton and Fahlstrom point out that there is a common belief that hypercholesteremia and low basal metabolism are reciprocal findings in thyroid deficiency; that hypercholesteremia, in the absence of other causes, points more to thyroid deficiency than does a low basal metabolism; that the blood cholesterol estimation may provide a guide in the treatment of thyroid disease, and that true thyroid deficiency is always accompanied by hypercholesteremia. Hypercholesteremia is said, also, to occur in diabetes mellitus, nephrosis, chronic nephritis, pregnancy, obstructive jaundice, cancer, celiac disease and hemorrhagic and aplastic anemia. The authors surveyed 830 patients many of whom presented endocrine problems. Cholesterol and basal metabolism tests were performed on all patients. Forty per cent of 334 cases showed low metabolism, and an insignificant percentage, 0.84 per cent or 7 cases, hypercholesteremia. Such a disproportion throws serious doubt on the value of cholesterol determinations as guides in hypothyroidism. Other factors besides the thyroid can be responsible for low basal metabolism. However, the size of this series studied—the majority of whom had some endocrinopathy—makes it unlikely that the cholesterol test per se has any but academic value as a routine test in problems of internal medicine. The series studied contained 15 diabetic persons, none of whom showed hypercholesteremia. A consecutive survey of 50 patients with low basal metabolism, minus 20 per cent or lower, showed 48 with normal cholesterol, 1 with low and 1 with hypercholesteremia. The latter patient was the only 1 of 7 with hypercholesteremia with a basal metabolism of over minus 20 per cent. The authors conclude that the blood cholesterol test is of little or doubtful value as a routine laboratory procedure in medical practice, but it may be of value in true myxedema or in certain specific indications.

**Biologic Assay of Different Types of Toxoid.**—According to Greenberg and Roblin different kinds of toxoids—e. g., fluid and alum precipitated—as well as toxoids of similar composition prepared by different manufacturers, vary widely in their immunizing ability. Thus there is need for a system of control whereby preparations for prophylaxis of diphtheria are assayed in terms of a standard preparation. The authors report studies that they carried out in order to establish a standard diphtherial toxoid and a procedure for assay of diphtherial toxoids. They describe three methods which are of about equal value when judged by the limits of error in individual tests and by assays of toxoids of known potency. Economy in the use of animals and other practical considerations will greatly influence the choice of test. The authors used the method that involves challenging with the skin test dose. Preliminary experiments conducted by them with toxoids from different manufacturers tended to confirm Prigge's observations and criticisms regarding the value of Lf determinations as tests of immunizing efficiency. Commercial laboratories with toxoids of uniform make and composition might be justified in using Lf determinations as an indication of immunizing efficiency providing the general potency of their toxoids has been well established with animal tests. Control laboratories, however, would not be so justified, since the toxoids from different manufacturers will probably vary considerably as a result of production methods. One provisional standard was used for testing all types of toxoid throughout this study, and, for convenience, an arbitrary unitage was established and the toxoids assayed are reported in terms of units.

**Adrenocorticotropic Hormone in Myasthenia Gravis.**—Soffer and his co-workers treated 1 woman aged 29 with myasthenia gravis and a thymic tumor by intramuscular administration of 40 mg. of anterior hypophysial adrenocorticotropic hormone (ACTH) daily in four divided doses for four days with a total dose of 160 mg. Treatment resulted in a pronounced decrease in the size of the tumor, a decided improvement in the clinical symptoms and elimination of the daily necessity for prostigmine. The decrease in the size of the tumor lasted for approximately three weeks, by the end of which time it regained its previous size. The improvement in symptoms continued for forty-six days after the four day course with the adrenocorticotropic factor was completed. During this period there has been a progressive reduction in the daily requirement of prostigmine, and during the past two weeks none at all has been required. It is not expected that the clinical improvement will continue indefinitely. The adrenocorticotropic factor resulted in some decrease in the urinary excretion of water, sodium and chlorides. Fluid retention and hemodilution were observed. There was a decided increase in the urinary secretion of neutral 17-ketosteroids and of 3-keto-delta-4-pregnene compounds. After the injection of adrenocorticotropic hormone there occurred a slight decrease in the urinary excretion of creatine and a pronounced reduction in the excretion of creatinine. The administration of this hormone was followed by a considerable increase in the total white blood cell count, due essentially to a pronounced increase in both the percentage and the absolute numbers of polymorphonuclear leukocytes. In addition, there was a reduction in the absolute number of lymphocytes.

**Availability of Amino Acids in Foods.**—Kuiken and Lyman maintain that the nutritive value of a protein is dependent not only on its content of essential amino acids but on the biologic availability of these amino acids as well. Incomplete digestion and absorption of an essential amino acid alters the effective composition of a food protein. The ultimate synthesis of body protein from the amino acids made available through digestion and absorption is dependent on a third factor, namely, the simultaneous appearance in the blood stream of each of the essential amino acids in suitable proportions. Protein synthesis does not occur unless a complete mixture of the essential amino acids is present at one time. The authors investigated the availability of all 10 of the essential amino acids in several food stuffs. They found that all 10 of the essential amino acids in roast beef are completely available to the rat. Wide variations occurred in the availability of the individual amino acids in cottonseed flour. Lysine in this protein source was only 65 per cent available. The corresponding value for arginine in the same sample was 93 per cent. The availability of each of the essential amino acids in wheat and peanut flour was found to be relatively high. For wheat the values ranged from 92.2 to 98.8 per cent, and for peanut flour from 94.8 to 99.5 per cent.

**Hyaluronidase in Fluid Administration.**—Schwartzman and his associates point out that administration of fluids to infants and young children has always been a problem in treating dehydrated babies. The enzyme hyaluronidase increases the rate of fluid absorption twelve times. This action is explained by the fact that hyaluronidase, a mucolytic enzyme, acts on and depolymerizes the mucopolysaccharide, hyaluronic acid. This is the gel present in the ground substance of connective tissue, which acts as a tissue barrier to fluid diffusion. Studies on adults and children revealed that hyaluronidase had no harmful effect on the patients. The extent and duration of the pain and swelling associated with clysis were greatly reduced by use of the enzyme. No alteration in body physiology was detected. It greatly facilitated absorption of all solutions used. The rate of absorption was practically identical for all patients, whether ill or not. Continuous clysis for at least five days could be given, with the needle shifted after the third day. Hyaluronidase proved of great value in the treatment of dehydrated infants. The substance would be of even greater value if it were purified so as to decrease the sensitivity factor.

**Generalized Vaccinia.**—Mustard and Hendrick direct attention to the severe vaccination complication known as generalized vaccinia. Thirty-six cases of this complication occurred in the mass smallpox vaccination undertaken in New York. Fifteen of these 36 patients, who manifested generalized vaccinial lesions, were admitted to the Willard Parker Hospital for Contagious Diseases in April and May, 1947, and these cases are reviewed in this paper. Eight of the 15 patients had not themselves been vaccinated against smallpox, but the unvaccinated group had been exposed to recently vaccinated members of their respective families. Eleven of the 15 patients gave a history of infantile atopic eczema. One patient receiving antisyphilitic therapy had an arsenical dermatitis. Two others had concurrent dermatoses, eczemoid in character but not specifically classified, while in the last patient the vaccinia was superimposed on varicella. The authors make recommendations for treatment. This includes suppression and prevention of secondary infection by the parenteral use of penicillin and saline compresses or penicillin ointment locally; prevention of further allergic reactions by removing from the diet the usual allergenic foods; prevention of further autoinoculation through restraint of infants from scratching, and maintenance of adequate hydration and of proper balance of body electrolytes. The authors conclude that patients with eczema and burns should not be vaccinated, nor should they remain in the same household with those recently vaccinated. Postvaccination complications in atopic eczema strongly suggest the advisability of vaccination during the first few months of life before the onset of most allergic skin conditions and before the infant is able to scratch. Persons to be vaccinated against smallpox should be questioned concerning active eczematous conditions in themselves or in members of their household. In the presence of the first condition the vaccination should be postponed until subsidence of the eczema. In the presence of eczema in a member of the household, the vaccinated person should live apart from the eczematous person until completion of the vaccination reaction.

**Treatment of Epidemic Vomiting.**—Bradley says that, although vomiting is a common initial symptom of acute infectious diseases of children, cases are often encountered in which it is difficult to find evidence of infection that is responsible for the vomiting. In Baltimore and its environs it has been the experience of pediatricians and general practitioners to see patients who repeatedly vomit for twenty-four hours or longer without exhibiting positive physical findings. The syndrome, while most prevalent in children, also occurs in adults. It has a rather striking seasonal incidence, being seen almost entirely during the months of October and November. A previously well child will suddenly begin to vomit. The infectiousness of the disease is illustrated by the rapid appearance of vomiting in other members of the family. Abdominal pain is often encountered and is localized in the left quadrant. It is fleeting in type and not too severe. The umbilicus is also given as the site of pain. The stools, seldom numbering more than three per day, are light in color, almost white, and have an extremely foul odor, which, with proper dietetic measures, disappears in four to five days. Transient glycosuria is frequent. Three cases are presented. The temporary derangement of the carbohydrate metabolism in the first 2 cases suggested low threshold diabetes, but this was ruled out by course and blood sugar check. The author has observed in his practice 773 cases of this clinical entity. A high carbohydrate intake is desirable. "coca-cola" syrup in teaspoon doses is given at intervals of fifteen to thirty minutes until three or four doses have been retained. Then, one teaspoonful is given every three hours for the next forty-eight hours. After the initial treatment with "coca-cola" syrup, the patient is permitted such foods as apple sauce, gelatin products, precooked cereals with only added sugar, toast or crackers, and jelly. The author has found this treatment highly satisfactory.
